## 42 **1 Introduction**

43 ENTSOG has produced a number of usage profiles [AS4UP, WSUP, INTUP] to support the  
44 implementation of the common data exchange solutions defined in the Network Code on  
45 Interoperability and Data Exchange [CR2015/703]. AS4, which is used for document-based  
46 data exchange, and SOAP/HTTPS, which is used for integrated exchange, support machine-  
47 to-machine exchange of structured information. To use these solutions successfully, TSOs  
48 and their counterparties need to configure various communication parameters in their  
49 communication products. Many of these parameters are pre-defined in the ENTSOG  
50 specifications and can be inferred by referencing the applicable specification version, but  
51 others are unique to specific parties and counterparties, and therefore need to be  
52 exchanged and configured between parties.

53 While it is possible to exchange communication configuration parameters bilaterally, this is  
54 inefficient and, if manual effort is involved, error-prone. Stakeholders in the gas sector have  
55 identified the need for a secure collaboration platform that allows parties to share and agree  
56 on such parameters, and to retrieve parameter sets in a structured format that can be  
57 imported or applied (semi-)automatically. The main identified benefits of the platform relate  
58 to setting up configurations for new parties and/or new services, where many parameters  
59 need to be set. The platform would therefore complement and serve a purpose different  
60 from the ebCore Agreement Update feature, which supports updates of existing  
61 configurations.

62 This document provides the following:

- 63 • An overview of requirements and key features that a central configuration portal  
64 should address. This is done in section 2. The exchange platform should allow parties  
65 to securely self-manage their parameter values, to selectively share these values with  
66 counterparties and to link profiles to agreements.
- 67 • A specification of a set of data elements for data exchange configuration parameters.  
68 This is discussed in section 3, which groups and defines the various parameters.
- 69 • A specification of functionality to export partner profiles and agreements. The  
70 exchange platform should allow parties to download parameters in structured  
71 formats. Vendors or systems integrators may use this functionality to (semi-  
72 )automatically configure communication. This is discussed in section 4.
- 73 • A specification of a Usage Profile of a draft standard, ebCore CPPA3, that can be used  
74 in the export function. This is done in section 5.

75 ENTSOG does not currently intend to develop or host this platform, but encourages its  
76 stakeholders, and stakeholder communities such as EASEE-gas, to develop and operate such  
77 a platform.

## 78 **2 Required Features**

79 The collaboration platform is to allow gas sector parties to maintain, exchange and agree on  
80 communication configuration data securely. Since TSOs exchange data among themselves,  
81 but also with other market participants, the platform should be open to all relevant parties  
82 in the gas business. The platform is useful if its users can serve as “one stop shop” to  
83 configure configuration with all or the vast majority of their counterparties.

84 The collaboration platform needs a formal identification system for parties and therefore  
85 identifies parties using their EIC code, as issued by ENTSOG and other issuing agencies. EIC  
86 codes are unambiguous and used as party identifier header values in AS4 messaging.

87 The collaboration platform should allow parties to provide and maintain their configuration  
88 parameters themselves. A self-service model avoids unnecessary delays, puts those  
89 responsible for data and data quality in charge of managing that data, and minimizes the  
90 operational costs of the platform.

91 The collaboration platform should allow sharing data where needed, but limit unnecessary  
92 sharing where possible. Parties exchange data in support of business processes with  
93 counterparties. The platform should allow parties to specify who their counterparties are,  
94 i.e. who they send messages to and who they receive messages from. This information can  
95 then be used to control the visibility of the data in the platform: configuration data is only  
96 shared among parties who are each other’s counterparties, but otherwise confidential, and  
97 agreements can only be formed among counterparties.

98 By analogy to human-to-human communication, the collaboration platform is more like a  
99 social network (in which people can share selectively, self-organize in private groups) than to  
100 email (which offers ad hoc any-to-any data sharing but no controls on visibility and sharing,  
101 and no concept of a communication agreement). Market communication is based on  
102 party/counterparty relations. These relations are typically stable rather than ad hoc, but not  
103 fully static, as players still enter or leave the market and companies may reorganize.

104 The collaboration platform is most useful if it allows all relevant parameters to be  
105 maintained. This includes parameters specific to the party, the communication protocol  
106 profile parameters, network and network security configuration, certificate sets, business  
107 process relations, agreement parameters and delegation information. A full overview and  
108 categorization of data exchange parameters is provided in section 3.

109 The platform should be able to support the full lifecycle of data communication. Companies  
110 periodically update their communication services and configuration parameters change  
111 accordingly. They may take on new roles, and outsource others. Companies also have other  
112 environments than their production systems, and need counterparty data to configure each  
113 of them, and need to be able to indicate in which intervals environments and configuration  
114 sets are valid.

115 The data that is managed in the collaboration platform is used in communication and  
116 networking systems. Since the data is structured and even minor errors can cause  
117 communication failures, it is important that the data can exported (or downloaded) in a (or  
118 in a selection of) structured electronic format(s). This is further addressed in section 4.

119 The platform can only be trusted if its operation is secure, all access to and use of its services  
120 is authenticated and authorized and all operations are logged and monitored. Each company  
121 registered to the platform should be able to manage which employees can use the platform  
122 on its behalf, and which operations they can perform.

### 123 **3 Data Exchange Parameters**

124 The ENTSOG data exchange specifications describe the use of data exchange solutions for  
125 various types of exchanges. These solutions are parameterized, meaning they need to be  
126 provided with configuration parameters to function appropriately. This section provides an  
127 overview and basic set of configuration data elements. The elements are grouped to support  
128 common reuse patterns:

- 129 • Party parameters
- 130 • (Sub) Profile parameters
- 131 • Networking and Network security parameters.
- 132 • Certificate sets.

133 The grouping provides support and flexibility for real-life data exchange situations and  
134 covers all parameters needed for the ENTSOG document-based and integrated exchanges.

135 Examples of some supported situations, not exclusive of others, are:

- 136 • A party has a “test” and a “production” environment for document-based exchange.  
137 This is handled as two (sub) profiles, with different endpoints hosted on different  
138 servers with different IP addresses and possibly different certificate sets.
- 139 • A party has two “production” environments for document-based exchange that are  
140 the same except that the first expires a month after the second is activated and that  
141 they are linked to different certificate sets. This can occur during a certificate  
142 switch period.
- 143 • A party has a “production” environment for document-based AS4 exchange and  
144 another “production” environment for integrated data exchange profile B.
- 145 • A party has two (sub) profiles that are both for the “test” environment. One is the  
146 regular test environment; the other is being used to test a new vendor product that  
147 the party will migrate to.

148 Parameters that have fixed values defined in the ENTSOG specifications are not covered in  
149 this overview. Instead, each (sub) profile is labelled with the type and version of applied data  
150 exchange solution. When configuring a generic, off-the-shelf communication system (i.e. not  
151 an ad hoc solution for an ENTSOG profile), users therefore need to combine the data  
152 elements specified in this section and the preconfigured values.

153 Note that a secure configuration exchange platform will need to manage other data, for  
154 example administrative data and authorizations, to support its own operation and use. This  
155 section only covers the data elements to be used to configure exchanges following the  
156 ENTSOG data exchange specifications.

157 This version of this document is focussed on document-based exchange. In principle, the  
158 approach could be extended to integrated and interactive exchange, though details and  
159 technologies used would be different.

### 160 **3.1 Party Parameters**

161 Party parameters provide information about a TSO or other company that is independent of  
162 data exchange solution.

163 This group also includes contact information which obviously is not directly used in a  
164 communication system, but can be useful in case of trouble-shooting.

Parameter	Description	Cardinality
Party Name	Name of the party	1
Party Identifier	EIC code of the party	1
Party Contact	A list of contacts for the party. Each contact has a type (e.g. "business contact", "technical contact") and one or multiple communication addresses. Each communication address has a type (e.g. email address, telephone number) and value.	1..n
Party Role	The role the party may perform, encoded as an EDIG@S code value.	1..n
Counter Party Identifier	A list of EIC codes of the counterparties of the party	1..n

### 165 **3.2 (Sub) Profile Parameters**

166 For each party, multiple party (sub) profiles may be defined. A (sub) profile is valid in an  
167 environment, uses a (version of a) data exchange solution on a URI, is valid in a certain  
168 interval, involves a set of certificates and has a network (security) configuration.

Parameter	Description	Cardinality
Sub Profile Identifier	An identifier for the sub-profile (only needed internally for cross references from agreements)	1

Parameter	Description	Cardinality
Party Reference	Reference to party for which this is a sub-profile	1
Party Role	<p>The role of the party for which this is a sub-profile. Must be one of the roles party may perform.</p> <p>If none specified, the sub profile applies to all roles that party may perform</p>	0..n
Environment	The environment for which the sub profile provides values, e.g. "acceptance" versus "production"	1
Activation Date	Date and time from which the sub parameter set is valid	1
Expiration Date	Date and time until which the sub parameter set is valid	1
Data Exchange Solution	<p>Indication which data exchange solution is used. Possible values are ENTSOG AS4, ENTSOG Integrated Data Exchange Profile A, B or C.</p> <p>Other values can be used for other solutions (e.g. legacy solutions, or solutions with NRA approval), such as EASEE-gas AS2.</p>	1
Data Exchange Solution version	Optional protocol version, useful in case future incompatible changes are made. Current version for ENTSOG AS4 is 3.5.	0..1
Data Exchange Product	<p>Vendor name and name and version of the product the solution is deployed on.</p> <p>Note: this element is for information only and parties are not required to disclose it. It may be useful for trouble shooting.</p>	0..1

Parameter	Description	Cardinality
Endpoint URI	HTTP or HTTPS URI for the endpoint. The domain name must be resolvable using DNS records ("A" for IPv4, "AAAA" for IPv6).	1
Network Security Parameter Set ID	Cross reference to a network Security Parameter Set	0..1
Certificate Set ID	Cross reference to a Certificate Set. Presence/absence dependent on data exchange solution used: not needed for interactive exchange. Referenced certificates must be valid in the validity interval of the profile.	0..1

169 **3.3 Network and Network Security Parameters**

170 A sub profile may be constrained to be used with a set of network parameters and network  
171 security parameters.

Parameter	Description	Cardinality
Network Security Parameter Set ID	Internal identifier for cross-referencing the network security parameter set	1
IPv4 supported	Boolean indicator that expresses if IPv4 may be used for communication	1
Client IP v4	IPv4 address or address range from which the endpoint initiates HTTP(S) connections Requires the IPv4 supported parameter to be true.	0..n
Server IP v4	IPv4 address or address range at which the endpoint accepts HTTP(S) connections Requires the IPv4 supported parameter to be true. A DNS "A" record MUST exist for the	0..n

Parameter	Description	Cardinality
	domain name used in the Endpoint and must resolve to an address in this range.	
IPv6 supported	Boolean indicator that expresses if IPv6 may be used for communication	1
Client IP v6	IPv6 address or address range from which the endpoint initiates HTTP(S) connections Requires the IPv6 supported parameter to be true.	0..n
Server IP v6	IPv6 address or address range at which the endpoint accepts HTTP(S) connections Requires the IPv6 supported parameter to be true.  A DNS "AAAA" record MUST exist for the domain name used in the Endpoint and must resolve to an address in this range.	0..n

172 **3.4 Certificate Sets**

173 A reusable set of certificates, to be used in conjunction with one or multiple (sub) profiles.

Parameter	Description	Cardinality
Certificate Set ID	Internal identifier for cross-referencing the certificate set	1
Signing Certificate (Chain)	An ordered list containing the leaf signing certificate, any intermediate certificates and the Certification Authority certificate.	1
Encryption Certificate (Chain)	An ordered list containing the leaf encryption certificate, any intermediate certificates and the Certification Authority certificate.	1
Server Certificate (Chain)	An ordered list containing the TLS leaf	0..1

Parameter	Description	Cardinality
	server authentication certificate, any intermediate certificates and the Certification Authority certificate.	
Client Certificate (Chain)	An ordered list containing the TLS leaf client authentication certificate, any intermediate certificates and the Certification Authority certificate.  Note: TLS client authentication is allowed, but not recommended in ENTSOG data exchange solutions.	0..1

### 174 **3.5 Business Process Relations**

175 Business process information is provided in the ENTSOG Service Action table [AS4MAP],  
176 which lists, for each pair of roles, the types of EDIG@S or other documents that can be  
177 exchanged between them. From that table, in combination with the information on roles  
178 performed by parties, the relevant AS4 parameters (Service, Action, From Role, To Role) and  
179 the EDIG@S Document Type can be inferred. By listing roles for parties, and listing  
180 counterparties for parties, all potential exchanges between parties can be computed.

181 A potential future enhancement could be to allow parties to more precisely indicate which  
182 versions of which business processes they support, and the relevant (versions of) document  
183 types exchanged in these processes.

### 184 **3.6 Agreement Parameters**

185 ENTSOG AS4 uses the AS4 agreement concept and requires the AS4 agreement reference  
186 header to be present in AS4 messages. This allows its users to handle certificate switches in a  
187 much more flexible way than the previous AS4 practice. As both involved parties may have  
188 multiple different (sub) profiles, linking to distinct certificate sets, an agreement is a relation  
189 at the sub-profile layer rather than the party layer.

Parameter	Description	Cardinality
Party Sub Profile Reference	A reference to a sub-profile of a party	1
Counterparty Sub Profile Reference	A reference to a sub-profile of another party	1

Parameter	Description	Cardinality
An agreement sequence number	An integer that indicates a version of an agreement.	1
Activation Date	Date and time from which the delegation is valid. Must be compatible with the activation dates of the parties involved.	1
Expiration Date	Date and time until which the delegation is valid. Must be compatible with the expiration dates of the parties involved.	1

190 Note that the referenced (sub) profiles must be of the same type. A “test” agreement must  
 191 be between two “test” (sub) profiles and a “production” agreement between two  
 192 “production” (sub) profiles. It is not possible to have an agreement involving a “test” party  
 193 profile and a “production” counterparty profile.

### 194 **3.7 Delegation**

195 Where normally organizations operate a messaging gateway to send and receive messages  
 196 to their counterparties, sometimes organizations do not create or receive messages  
 197 themselves, but use third party service providers that send and receive messages on behalf  
 198 of and for them. Two situations can be distinguished:

- 199 1. Impersonation: in this situation, the third party sends and receives messages to the  
 200 counterparties of the customer using the identity of its customer. For configuration  
 201 and the configuration exchange platform, this is not different from the usual  
 202 situation. The profile configuration is still registered with the EIC code of the  
 203 customer.
- 204 2. Delegation: in this situation there are no messaging profiles for the customer in the  
 205 portal, but there are for their service providers. To allow counterparties to know that  
 206 a party uses a service provider, so that they can configure messaging with that  
 207 service provider, an explicit delegation table can be used.

208 The delegation relation has the following properties:

Parameter	Description	Cardinality
Delegating Party Profile	Reference to a registered party	1

Parameter	Description	Cardinality
Delegating Party Role	The role for which the party delegates communication	0..n
Delegated Party Profile	Reference to a registered party	1
Activation Date	Date and time from which the delegation is valid	0..1
Expiration Date	Date and time until which the delegation is valid	0..1

209 Note that the model makes it possible for parties to delegate processing for some roles but  
210 not for others. Also note that using multiple records with different activation/expiration  
211 dates, it is possible to describe a switch from one service provider to another, or to describe  
212 a outsourcing switch from an in-house solution to a service provider.

213 Delegation information is not messaging configuration information. Rather, it defines  
214 constraints on relations between sender and receiver identifiers at message layer and at  
215 business document layer, which can be validated in middleware or in business systems. All  
216 configuration data for the actual exchange with the delegated party is not included in the  
217 table. That data is instead provided as a (sub) profile of the delegated party. So, if party A  
218 wants to exchange data with a party B that delegate to a service provider X, A must  
219 configure an agreement with X. If A also outsources its data exchange to a service provider Y,  
220 then X and Y must have an agreement.

#### 221 **4 Structured Export**

222 A collaboration platform in which parties can self-manage their configuration parameters  
223 and their relations with counter-parties is already a very useful first step. A next step is to  
224 allow configuration data to be exported into a structured XML format, which can be  
225 imported into communication software to set parameter sets efficiently. This eliminates  
226 manual data entry and avoids the associated potential data entry errors.

227 The OASIS ebCore draft CPPA3 XML schema [**Error! Reference source not found.**] and  
228 specification [**Error! Reference source not found.**] provide a standard mechanism to encode  
229 partner profile and agreement information for multiple communication protocols, including  
230 AS2 and AS4. It can be used as a vendor-independent intermediate format to export data  
231 managed in a secure configuration sharing environment into proprietary formats and  
232 interfaces of communication products.

233 In addition to exporting to a (draft) standard format, the secure central platform may also  
234 offer direct exports to proprietary formats.

#### 235 **4.1 CPPA3 Profile**

236 The OASIS ebCore draft CPPA3 XML schema [**Error! Reference source not found.**] and  
237 specification [**Error! Reference source not found.**] provide a structured XML format for party  
238 profile and party agreement configuration. As is common with standard formats that are  
239 intended to be used in very different contexts, it offers many options and typically benefits  
240 from being profiled. Such profiling may cover both functionality to be implemented in  
241 products and conventions to be adopted by users.

242 For the secure gas configuration data exchange platform, a usage profile is provided in  
243 section 5. A proof-of-concept that illustrates the use of ebCore CPPA3 and that implements  
244 this usage profile is published as open source, under the MIT license, on the public Internet  
245 [AS4CPOC]. It includes sample code to generate CPP and CPA documents for parties.

#### 246 **4.2 Profile Export**

247 A (Sub) Party parameter set, as described in section 3.2, can be exported together with  
248 referenced party information (see section 3.1), network and network security information  
249 (see section 3.3) and security sets (see section 3.4) as an ebCore CPPA3 CPP document.

250 A CPP can capture all relevant information for AS2 exchanges, and could therefore be used  
251 to configure EASEE-gas AS2 exchanges. However, for ENTSOG AS4 the export the CPP  
252 structure is insufficient as it does not include agreement-related information.

#### 253 **4.3 Agreement Export**

254 For ENTSOG AS4, which uses the AS4 concept of “agreements”, the configuration for a  
255 partner is to be derived from an Agreement parameter set, as described in section 3.6, along  
256 with data from referenced profiles (see section 3.2), party information (section 3.1), network  
257 and network security information (see section 3.3) and security sets (see section 3.4).

258 The main difference to configuration based on party profiles is that with agreements,  
259 multiple agreements can be active at the same time. Each of them relates to certificates  
260 specified in the certificate sets of the associated profiles. Furthermore, an agreement has an  
261 identifier that is included in the AS4 message as the value of an AS4 header. This allows  
262 receivers of AS4 messages to select the agreement that applies to the message, and process  
263 it accordingly.

#### 264 **4.4 Delegation Export**

265 The draft CPPA3 schema has a concept called “delegation channels” that delegation  
266 information can be mapped to. This concept can be used in CPA documents in which one or  
267 both parties P1 and or P2 use at least one service provider S. The CPA XML structure then  
268 has P1 as the agreement Party and P2 as the agreement counterparty. For the party P that  
269 delegates messaging to S, there will be a channel that simply expresses that any of P’s

270 actions bound to send will use S as the sender or receiver. Whether that communication  
271 uses AS2 or AS4 or other aspects of the configuration are determined by P's configuration  
272 for S.

273 The users of this delegation information are not the AS2 or AS4 messaging gateways, but  
274 business applications or middleware applications.

- 275 • A sender party P1 can use the information to determine that a EDIG@S message to  
276 P2 is to be sent to S instead of to P2 and therefore must use a messaging  
277 configuration for use with S. In this case, the messaging receiver (*AS2-To* in AS2 or  
278 *To/PartyID* in AS4) is different from the EDIG@S XML recipient.
- 279 • A receiver party P2 can use the information to determine that a EDIG@S message  
280 from S may (from a business point of view) be from a business party P1. This means  
281 that the messaging sender (*AS2-From* in AS2 or *From/PartyID* in AS4) identity is  
282 different from the EDIG@S XML recipient identity.

283 Alternatively, the delegation information can be exported in CSV or another tabular format  
284 that is simpler than the CPPA3 the XML format.

#### 285 **4.5 Network and Network Security Export**

286 The network and network security parameters are typically not used by the AS2 or AS4  
287 endpoints directly. Instead, they are used in rules on the company's firewall and configured  
288 by the company's network administrators, which are typically different people from the AS4  
289 system administrators. Although the CPP and CPA formats include the relevant information,  
290 a simpler and separate export format could be used. For example, for Linux one could  
291 generate a shell script that invokes the *iptables* command with the relevant options, or a  
292 simple file in CSV or another tabular format. These simpler exports could be handed over to  
293 network management for review and deployment.

### 294 **5 CPPA3 Usage Profile**

295 The following implementation guidelines are provided:

#### 296 **5.1 CPP and CPA**

297 CPPA3 defines two document types. CPP is an XML format for a party profile. CPA is a  
298 similar format for party agreements. They have similar structures and the latter can be  
299 formed automatically by unifying (merging) the content of two of the former.

300 A CPP has a `ProfileIdentifier`. This identifier serves the purpose of the (Sub) Profile  
301 Identifier specified in section 3.2. Its value is not used in AS4.

302 A CPA has an `AgreementIdentifier`. This identifier is used in AS4 and has an  
303 important role in ENTSOG AS4. Its content can be derived from the agreement sequence  
304 number (see section 3.6) and the party identifiers (see section 3.2).

305 A CPP MAY have an `allowed` attribute that points to a list of party identifiers. This list can  
306 be populated from the list of counter party identifiers (see section 3.1).

307 CPP and CPA have `ActivationDate` and `ExpirationDate` elements set based on  
308 values defined in 3.2 and 3.6.

## 309 5.2 Party Information

310 The CPPA3 `PartyInfo` element, which provides party information, is profiled as follows:

- 311 • The `PartyId` value for a party MUST be to the EIC Code for the party.
- 312 • The `PartyId/@type` attribute MUST be set to the fixed value  
313 `http://www.entsoe.eu/eic-codes/eic-party-codes-x`.
- 314 • The `PartyName` MUST be set to party's Party Name.

315 As an example, the following screenshot was taken from the ENTSOG approved EIC code  
316 section on ENTSOG's Website [EIC].

EIC PARTY CODES (X) <span style="float: right;">Last update on 2017-09-15</span>		
EIC Code	Party Name	Display Name
21X0000000010012	APX Gas NL BV	APX-GAS-NL
21X0000000010020	APX Gas Zeebrugge BV	APX-GAS-ZEEBRUGG

317  
318 The first entry on this line can therefore be represented in CPPA3 as the following  
319 `PartyInfo` content:

```
320 <cppa:PartyName xml:lang="en">APX Gas NL BV</cppa:PartyName>
321 <cppa:PartyId type="http://www.entsoe.eu/eic-codes/eic-party-codes-x"> 21X0000000010012</cppa:PartyId>
```

322 Certificates used for message layer signing and encryption MUST be provided as  
323 `Certificate` elements containing XML Signature `KeyInfo` elements. Within the  
324 `KeyInfo`, the full certificate chain MUST be provided, in order, from the leaf certificate to  
325 the issuing Certification Authority's root certificate, as `X509Certificate` elements.  
326 Furthermore, a `CertificateDefaults` element MUST be included which MUST include  
327 a `SigningCertificateRef` and an `EncryptionCertificateRef` element, which  
328 reference a `Certificate`.

329 Note that in CPPA3, definition and use of certificates are separate. So, if a single certificate is  
330 used for both signing and encryption, only one definition must be provided, to which there  
331 are two references.

332 In a CPP, there is only a `PartyInfo` element. In a CPA, there is also a  
 333 `CounterPartyInfo` element. It relates to the other party in the agreement. It has the  
 334 same structure as the `PartyInfo` element.

### 335 **5.3 Service Specification**

336 All companies engaged in gas sector business can participate in one or more roles. The  
 337 ENTSOG AS4 Mapping Table [AS4MAP] provides a tabular definition of all data exchanges  
 338 specified in all ENTSOG Business Requirements Specification (BRS) document. Therefore, it is  
 339 possible to compute the full set of potential exchanges of any gas company by selecting the  
 340 exchanges in which the sending party role or the receiving party role is one of the roles the  
 341 company may perform.

342 The following example specifies the exchanges from the company in the `ZSO` role, where the  
 343 counterparty is a `ZTZ`. According to the mapping table, one of the services among these  
 344 roles is the `A08` role. For this service, many action bindings are to be specified. Apart from  
 345 the binding for `A08`, other service bindings may follow. (Both further discussed after this  
 346 example).

```

347 <cppa:ServiceSpecification>
348   <cppa:PartyRole name="ZSO"/>
349   <cppa:CounterPartyRole name="ZTZ"/>
350   <cppa:ServiceBinding>
351     <cppa:Service type="http://edigas.org/service">A08</cppa:Service>
352     <!-- a number of action bindings, see below -->
353   </cppa:ServiceBinding>
354   <!-- other service binding definitions follow -->
355 </cppa:ServiceSpecification>
  
```

356 Within a service, separate `ActionBinding` elements **MUST** be provided for each message  
 357 exchange specified in the AS4 mapping table for the pair of roles. The following example  
 358 shows the content for the `A08` service in the above example.

```

359 <cppa:ActionBinding sendOrReceive="send"
360   action="http://docs.oasis-open.org/ebxml-msg/as4/200902/action" id="ab_1_1">
361   <cppa:ChannelId>ch_send</cppa:ChannelId>
362   <cppa:PayloadProfileId>pp_ALW</cppa:PayloadProfileId>
363 </cppa:ActionBinding>
364 <cppa:ActionBinding sendOrReceive="receive"
365   action="http://docs.oasis-open.org/ebxml-msg/as4/200902/action" id="ab_1_3">
366   <cppa:ChannelId>ch_receive</cppa:ChannelId>
367   <cppa:PayloadProfileId>pp_ALU</cppa:PayloadProfileId>
368 </cppa:ActionBinding>
  
```

369 A party acting in a role may be either the sender or the recipient in the exchange. This is  
 370 reflected in the `sendOrReceive` attribute value. In the example, there is one exchange  
 371 from the party to the counterparty and one in the reverse direction.

372 In the ENTSOG AS4 profile [AS4UP], it is specified that the `action` is fixed to be the AS4  
 373 default action. There may be multiple bindings for this action in the service, which are only  
 374 differentiated by the type of document exchanged. In a CPPA3 document there are

375 therefore multiple bindings for the action. In theory, multiple action bindings MAY involve  
 376 the same document. For this reason, CPPA3 does not include its payload specification as  
 377 child content of the `ActionBinding` element but instead has a `PayloadProfileId`  
 378 element whose content is an XML IDREF to a separate reusable definition. The value of the  
 379 identifier can be any XML ID, such as `pp_ALW` and `pp_ALU` in the example below.

380 Similarly, there is a cross-referencing `ChannelId` element that specifies the  
 381 communication channel to be used for the exchange (see section 5.5).

## 382 **5.4 PayloadProfile**

383 In CPPA3, payload definitions can be specified in a `PayloadProfile` element. This  
 384 element has a mandatory `id` attribute that is the target of the `PayloadProfileId`  
 385 element. To support protocols like AS4 that may include multiple payloads, in CPPA3 the  
 386 `PayloadProfile` element includes as many `PayloadPart` elements as are needed. For  
 387 each part, the minimum and maximum cardinality is specified using attributes. For ENTSOG  
 388 AS4, where the payload is always a single EDIGAS document, the `PayloadPart` element  
 389 MUST contain a single `PayloadPart` element in which the `PartName` element has the  
 390 fixed content "businessdocument". It also MUST contain and a fixed  
 391 `MIMEContentType` element with fixed content "application/xml" and a fixed single  
 392 `Property` element with fixed name "EDIGASDocumentType", minimum and maximum  
 393 occurrence of "1" and a `value` attribute.

```

394 <cppa:PayloadProfile id="pp_ALU">
395   <cppa:PayloadPart maxOccurs="1" minOccurs="1">
396     <cppa:PartName>businessdocument</cppa:PartName>
397     <cppa:MIMEContentType>application/xml</cppa:MIMEContentType>
398     <cppa:Property maxOccurs="1" minOccurs="1" name="EDIGASDocumentType" value="ALU"/>
399   </cppa:PayloadPart>
400
  
```

401 The value of the `value` attribute MUST be set to the EDIG@S Document Type Code  
 402 specified for the exchange in the AS4 Mapping Table.

## 403 **5.5 ebMS3Channel**

404 For document based exchange, EU regulations [CR2009/715] specify that the common  
 405 solution is AS4. Therefore, all exchanges use the AS4 protocol. To configure AS4, which is a  
 406 profile of ebMS3, CPPA3 provides the `ebMS3Channel` element. This element provides  
 407 configurability for all ebMS3 features using sub-elements, including reliable messaging, WS-  
 408 Security, error handling etc. However, the ENTSOG AS4 Usage Profile [AS4UP] provides fixed  
 409 values for these features.

410 To support usage profiles, and to obviate the need of entering predictable and repetitive  
 411 values, CPPA3 provides a `ChannelProfile` element, the content of which is a mutually  
 412 understood identifier of a usage profile.

413 These implementation guidelines require that the `ChannelProfile` element MUST occur  
414 and that its content MUST be set to “`http://www.entsog.eu/AS4-USAGE-`  
415 `PROFILE/v3/UserMessageChannel`”. This value is a URI identifier, which is used for  
416 identification only. It does not resolve to a page on the ENTSOG site. The identifier identifies  
417 the use of version 3 of the ENTSOG AS4 Usage Profile. Apart from this element, other child  
418 elements MUST NOT be used.

419 Using the `transport` attribute, an `ebMS3Channel` references a transport. For AS4, this is  
420 always an `HTTPTransport`. Since there are different transports for incoming and outgoing  
421 messages, a CPPA3 document MUST include two `ebMS3Channel` elements, one for  
422 incoming and one for outgoing messages. They have different `id` attribute values (so they  
423 can be referenced unambiguously) and different `transport` attribute values (since they  
424 reference distinct transports). Otherwise, there are no differences between the two  
425 definitions.

```
426 <cppa:ebMS3Channel id="ch_send" transport="tr_send">
427   <cppa:ChannelProfile
428     >http://www.entsog.eu/AS4-USAGE-PROFILE/v3/UserMessageChannel</cppa:ChannelProfile>
429 </cppa:ebMS3Channel>
430 <cppa:ebMS3Channel id="ch_receive" transport="tr_receive">
431   <cppa:ChannelProfile
432     >http://www.entsog.eu/AS4-USAGE-PROFILE/v3/UserMessageChannel</cppa:ChannelProfile>
433 </cppa:ebMS3Channel>
434
```

435 Note that there also exist implicit other channels, in addition to these two. AS4 errors and  
436 receipts use different channels, viz. the HTTP backchannel. These channels are considered  
437 implied by the reference of the ENTSOG AS4 Usage profile using the `ChannelProfile`  
438 element. For use in AS4 products these implicit channels, and the configuration of all  
439 channels, may need to be made explicit. One way of doing that is to extend the CPPA3  
440 document by adding the implied content, under the control of the `ChannelProfile`  
441 value. The AS4-CPPA3 proof-of-concept [AS4CPOC] shows how this could be done in CPPA3,  
442 using an open source CPPA3 library module.

## 443 **5.6 HTTPTransport**

444 These implementation guidelines REQUIRE that each CPPA3 document has two  
445 `HTTPTransport` elements.

446 The first covers exchanges where the party specified in the `PartyInfo` element sends the  
447 AS4 message, and is therefore using HTTP in client capacity. In a CPP, it MUST contain a  
448 `ClientIPv4` and/or `ClientIPv6` child element that specifies the client IP addresses (or  
449 address ranges) from which the transport will be initiated.

450 The second transport covers the case where it receives the AS4 message, and is therefore  
451 using HTTP in server capacity. In a CPA, it MUST contain an `Endpoint` child element that

452 specifies the URL at which the message handler accepts incoming connections. It MAY  
453 contain `ServerIPv4` and/or `ServerIPv6` child elements.

454 In a CPA, both `HTTPTransport` elements contain elements from both the party and the  
455 counterparty, in either direction. They therefore MUST contain `ClientIPv4` and/or  
456 `ClientIPv6` children elements and an `Endpoint` child element.

457 For example, in a CPP, these two `HTTPTransport` elements could look as follows:

```
458 <cppa:HTTPTransport id="tr_send">  
459   <cppa:ClientIPv4>5.2.3.4</cppa:ClientIPv4>  
460 </cppa:HTTPTransport>  
461 <cppa:HTTPTransport id="tr_receive">  
462   <cppa:Endpoint>https://tso5.eu/as4</cppa:Endpoint>  
463 </cppa:HTTPTransport>
```

464 In a corresponding CPA example, these two `HTTPTransport` elements could look as  
465 follows:

```
466 <cppa:HTTPTransport id="tr_send">  
467   <cppa:ClientIPv4>5.2.3.4</cppa:ClientIPv4>  
468   <cppa:Endpoint>https://tso1.eu/as4</cppa:Endpoint>  
469 </cppa:HTTPTransport>  
470 <cppa:HTTPTransport id="tr_receive">  
471   <cppa:ClientIPv4>1.2.3.4</cppa:ClientIPv4>  
472   <cppa:Endpoint>https://tso5.eu/as4</cppa:Endpoint>  
473 </cppa:HTTPTransport>
```

474 Just as there was a lot of implicit information in an `ebMS3Channel` element, there is  
475 information implicit in transport definitions. An example is that TLS is to be used in version  
476 1.2.

## 477 **5.7 Delegation**

478 In principle, CPPA3 can represent delegation information using its `DelegationChannel`  
479 element. A single CPP or CPA document can mix action bindings to `ebMS3Channel` and  
480 action bindings using `DelegationChannel`. However, as noted in section 4.4, simpler  
481 tabular formats may be of more practical use.

482 **6 Revision History**

Revision	Date	Editor	Changes Made
v0r1	2017-09-14	PvdE	First Draft for discussion
V0r2	2017-10-05	PvdE	Intermediate version for internal review
V0r3	2017-10-10	PvdE, JM	Editorial fixes added back in
