1 INTRODUCTION

The TYNDP 2024 Hydrogen Infrastructure Gaps Identification report (IGI report) aims at identifying regional infrastructure gaps within the assessed sets of hydrogen infrastructure assumed to be in place in a given year (i.e., hydrogen infrastructure level). IGI indicators are used for this identification.

This document is established in line with Article 13 of the TEN-E Regulation. Further details about its legal background, assumptions, modelling tools, and methodologies are provided in the TYNDP 2024 IGI methodology (Annex D2) that is cross-referencing to the TYNDP 2024 Implementation Guidelines (Annex D1) as well as to the TYNDP 2024 scenarios¹.

Infrastructure gaps identified in ENTSOG's hydrogen-related TYNDP 2024 IGI report may in some cases also be addressable by energy infrastructure solutions in other sectors like the electricity sector or the natural gas sector. This is the case for any infrastructure gaps identification that is focused on a specific energy vector. For electricity, ENTSO-E prepares the Identification of System Needs (IoSN) report, which is the equivalent to ENTSOG's IGI report.

There are two hydrogen infrastructure levels analysed as part of the IGI report (see section 3):

- ▲ A **PCI/PMI hydrogen infrastructure level** containing existing hydrogen infrastructure, FID hydrogen projects, and hydrogen projects on the Union list², modified by requests of the European Commission concerning import corridors.
- ▲ An **Advanced hydrogen infrastructure level** containing the PCI/PMI hydrogen infrastructure level as well as advanced hydrogen projects, modified by requests of the European Commission concerning import corridors.

The electricity infrastructure level considered in the IGI reflects the reference grid including generation and storage assets used in the NT+ scenario. Depending on time horizon (i.e., 2030 or 2040) different electricity projects will be considered to be part of the reference grid (as described in the Annex D1 section 2.3.2).

The analysis is performed for 2030 and 2040 for the TYNDP 2024 National Trends+ (NT+) scenario. Thereby, three indicators are used to identify regional hydrogen infrastructure gaps (see section 4).

¹ The TYNDP 2024 Annexes D1 and D2 are available on <https://tyndp2024.entsog.eu/downloads/>

² 6th Union list of Projects of Common Interest (PCI) and Projects of Mutual Interest (PMI) (i.e., 1st Union list under the revised TEN-E Regulation) as detailed in section B of Annex VII to the TEN-E Regulation.

2 FEEDBACK SECTION

2.1 FROM DRAFT TO FINAL TYNDP 2024

WHAT HAS HAPPENED SINCE THE DRAFT TYNDP PUBLICATION?

During the TYNDP 2024 cycle, five stakeholder consultations were held, covering TYNDP reports and supporting materials, like maps and data. This is higher than in previous cycles, resulting from the implementation of the updated TEN-E provi-

sions on stakeholder engagement. A wide range of stakeholders had the opportunity to ask questions and participate in discussions along the process. Recordings of corresponding webinars can be found in the 'Events' section of ENTSOG's website³.

WHY A FEEDBACK SECTION?

This section aims at gathering the feedback received from both ACER and the EC during the TYNDP 2024 process. It describes which part of this

feedback is already addressed in the final TYNDP 2024 and which is planned to be used in future cycles, indicating which process it will feed into.

2.2 ACER OPINION AND RECOMMENDATIONS

The content in the ACER Opinion on the [Hydrogen Infrastructure Gaps Identification report](#), of 27 May 2025, should be read together with its other Opinion documents on individual components of the TYNDP 2024, namely on the [Joint Scenarios report](#).

While ACER recognised the hydrogen IGI report as a key, trustworthy and robust tool in shaping the European hydrogen market, it also provided a number of recommendations for further improvement.

RECOGNITION OF IMPROVEMENTS

ACER recognises ENTSOG's efforts in addressing the challenges of developing methodology and producing analytical outputs for the future European hydrogen network – which not only is yet to be built, as well as subject to the development of dedicated

policy. It acknowledges that, compared to TYNDP 2024, ENTSOG improved stakeholder engagement, organising public consultations and made efforts to foster transparency and collaboration in the development of the underlying methodology.

³ <https://www.entsog.eu/events>

SHORT-TERM RECOMMENDATIONS

The ACER Opinion, received on 27 May 2025, provides for a number of short-term recommendations listed in the table below, in the order they appear in the ACER Opinion. The TYNDP topic to which these recommendations refer to are also indicated in the table below.

Nr.	ACER short-term recommendations	Explanation	Related TYNDP topic/report – paragraph in which the recommendation is handled
1.	Publish Simulation results with the assumption of unlimited import capacity as described in paragraph (40) of this Opinion.	<p>An analysis comparing different unlimited simulations is included in the final IGI for 2030 and 2040:</p> <ul style="list-style-type: none"> • unlimited internal pipeline capacity (no bottlenecks due to unlimited transmission connections between nodes) • unlimited storage (unlimited storage withdrawal, injection and working gas volume in existing storage countries) • unlimited internal pipeline capacity and unlimited storage (a combination of the above) • unlimited imports (unlimited import capacities for external EU supply defined in infrastructure level and years). 	Infrastructure Gaps Identification report – sections 6.2.2 and 7.2.2
2.	Publish Analysis with hypothetical infrastructure approach with a more detailed explanation of the methodology – chapter already indicated in the IGI report.	The explanations in the methodology (Annex D2) have not been reiterated in the IGI report. Instead, relevant references have been inserted in the IGI report text.	Infrastructure Gaps Identification report – sections 6.2.2 and 7.2.2
3.	In the final IGI report, relevant tables should be complemented with units for the lists of borders exceeding the threshold of IGI Indicator 1, as it is unclear whether the figures in the table represent units of days or EUR/MWh.	Missing units in tables 11, 18, 27 and 34 were updated. Figures in the tables are in days, to display number of days where thresholds are exceeded.	Infrastructure Gaps Identification report – sections 6.1.1.1, 6.1.2.1, 7.1.1.1 and 7.1.2.1
4.	Additional figures and graphs for a clearer presentation of examples in the Annex D2.	Graphical illustrations have been inserted into Annex D2, accompanying examples in sub-section 4 of Chapter 5.1 and in Chapter 5.2.	Annex D2 – Hydrogen Infrastructure Gaps Identification Methodology – sections 5.1, 5.2
5.	[...] an improvement of results presentation for the next process by presenting the results in a more interactive format, as an online dashboard, allowing the user to set the parameters/variables and obtain results based on that.	<p>An online visualisations platform is available at</p> <p>https://tyndp2024.entsog.eu/visualisation-platform/</p>	TYNDP 2024 website and TYNDP section of ENTSOG website – online visualisation platform

MEDIUM-TERM AND LONG-TERM RECOMMENDATIONS

The following table illustrates the medium and long-term ACER Opinion recommendation and the TYNDP (or ENTSOG) processes where they are tackled.

Nr.	ACER long-term recommendations (TYNDP 2024)	Related TYNDP/ENTSOG process
1.	<p>Streamline IGI report development process</p> <p>(Opinion – point 2, assessment – point 22)</p>	<p>TYNDP process / TYNDP Infrastructure Gaps Identification Report</p> <p>Recent TEN-E revisions added formal opinion and approval periods of up to 20 months to a cycle that should last between three and four years.</p> <p>The TYNDP 2024 Hydrogen IGI report was submitted to ACER on 10 March 2025. Key factors affecting its timeline included the joint Scenarios development, which received EC approval in January 2025, and the approval of the Hydrogen CBA methodology in February 2025. These approvals are essential as they provide core assumptions used in simulations and project assessments.</p> <p>To address process delays, ENTSOG began work on the Hydrogen IGI report in autumn 2024, using preliminary assumptions and simulation results. Until the relevant methodology and the 2024 Scenarios were formally approved, ENTSOG took into account feedback received during periodic exchanges with the EC and ACER in order to progress with the IGI simulations and report. While this allowed submission in March 2025, it caused duplicated work and a series of unnecessary simulation efforts. The guidance documents, produced before final CBA approval, were more extensive than needed, further prolonging the drafting and stakeholder validation processes.</p> <p>It must also be acknowledged that TYNDP 2024 in particular had an experimental nature, with a consolidated hydrogen project base, a new model, interlinking the hydrogen and electricity sectors, a new CBA methodology and an updated TEN-E process, all in the same cycle. In future, ENTSOG will consolidate on the experience from TYNDP 2024, as well as on the learnings from its exchanges with ACER and the EC.</p> <p>It must nevertheless be acknowledged that the increasing complexity of sector integration and the involvement of a growing number of stakeholders are making the TYNDP process lengthier.</p>
2.	<p>Redesign the approach for the identification of infrastructure gaps</p> <p>(Opinion – point 3, key findings and recommendations – point 7, ACER’s assessment – point 36)</p>	<p>TYNDP Infrastructure Gaps Identification Report – quantification of gaps</p> <p>It should be noted that the scenario values for hydrogen were determined by an expansion model as explained in the TYNDP 2022 Scenario report and its accompanying documents. However, for infrastructure gaps identification purposes, an interlinked model, adding the electricity grid to the hydrogen grid was also run after the scenarios were built, using the current hydrogen infrastructure levels, as well as the relevant electricity projects instead of the results of the expansion model that had delivered the scenario values. From these new simulations, the curves for hydrogen- and methane-fired power plants were retrieved, together with updated electrolytic hydrogen production values, to maintain consistency with the electricity TYNDP.</p> <p>However, the location of the hydrogen production as well as its distribution over the year can thereby also change. This can affect the optimal specifications of the European hydrogen infrastructure. Therefore, a per-border gap specification would provide an incomplete answer to the question of identifying optimal capacity needs, reflecting infrastructure needs only for part of any given year.</p> <p>With specific regards to cost information, this is requested from promoters for each PCI/PMI selection. Over cycles, ENTSOG gradually added cost-related elements in the data collection. For instance, in the 1st selection process under the most recent TEN-E revision, a specific de-aggregation requirement was added for new and repurposed sections of projects, as well as a break-down of investment costs by year. For non-PCI/PMI candidate projects, ENTSOG is required to respect the request for confidentiality of project information. Hence, any unit investment cost estimation for the purpose of filling-in infrastructure gaps would only be partially representative, of PCI/PMI applicant projects.</p>
3.	<p>Perform the IGI assessment under several scenario variants and sensitivity analyses</p> <p>(Opinion – point 3, key findings and recommendations – point 7)</p>	<p>TYNDP Infrastructure Gaps Identification Report – Choice of reference scenarios</p> <p>In TYNDP 2024, ENTSOG followed the European Commission’s guidance to solely focus on the National Trends+ scenario for IGI simulations.</p> <p>Four sensitivities were added to the final TYNDP 2024 Hydrogen IGI report, for distinct hypothetical situations with unlimited capacities. These were performed for both target-years and infrastructure levels.</p> <p>ENTSOG acknowledges that incorporating additional scenario variants and sensitivity analyses would provide a broader perspective, thereby potentially improving infrastructure planning. ENTSOG will continue exchanging with stakeholders, including the EC, ACER and ENNOH for the choice of scenarios and sensitivities for the TYNDP 2026 hydrogen IGI.</p>

Nr.	ACER long-term recommendations (TYNDP 2024)	Related TYNDP/ENTSO-G process
4.	<p>Reconsider measurement of security of the supply risk for hydrogen projects until the market matures</p> <p>(assessment – point 37)</p>	<p>TYNDP Infrastructure Gaps Identification Report – Stress-case assessment for hydrogen</p> <p>While IGI indicator 2.1 was designed to assess the curtailed hydrogen demand in DHEM and DGM for the reference weather year, indicator 2.2 provides a complementing assessment, of hydrogen demand curtailment in climatic stress cases.</p> <p>Even though the hydrogen market and infrastructure are in their early stages, the lessons learned from the gas and electricity sectors demonstrate the importance of stress testing in order to ensure credibility and to help identify bottlenecks before they turn into systemic risks.</p> <p>Additionally, hydrogen production will depend heavily on variable renewable generation, making it more exposed to extreme weather variability compared to today's gas system.</p> <p>Disregarding such weather-related stress-case scenarios – especially in the early stages of planning – risks underestimating flexibility and storage needs from the onset. It could lead to costly retrofits in the long run, damaging trust in a secure energy carrier – hydrogen.</p>
5.	<p>Pass from interlinked energy sector models to a unified model, improve the chosen starting grid for the IGI assessment and generally improve the alignment of assumptions with ENTSO-E</p> <p>(Opinion – point 3., assessment – sub-section 2.4.)</p>	<p>TYNDP Process / TYNDP Infrastructure Gaps Identification Report / PS-CBA</p> <p>In its previous opinion, on TYNDP 2022, ACER requested that ENTSOG implement the interlinked model jointly with ENTSO-E – with specific focus on electrolyser projects, to support individual project assessments, as well as their impact at grid-level for the purpose of the first PCI/PMI process under the revised TEN-E.</p> <p>In ENTSOG's TYNDP 2024, electrolyser projects are fully considered in the hydrogen infrastructure needs assessment. ENTSOG has performed, for the second consecutive time, electrolyser project assessment, to support the EC's second PCI/PMI selection under the revised TEN-E.</p> <p>While the interlinked model is under development between ENTSOG and ENTSO-E, the best approach continues to be the use of interconnected individual sector modelling, with successive data validation improvements over cycles. The Dual Hydrogen-Electricity Model (DHEM) was used for this purpose in TYNDP 2024.</p> <p>With regards to the cross-sectoral coverage of TYNDP assessments, the TYNDP 2024 PS-CBA included a dedicated indicator (B4) that measures benefits and costs across energy carriers for individual projects, including an electricity-hydrogen synergy measurement.</p> <p>ENTSOG is continually collaborating with ENTSO-E to ensure the same assumptions are used from the basis of TYNDP process, which are the Scenarios. Under the new Scenario Framework for TYNDP 2026, ENTSOG and ENTSO-E have been jointly working, in close cooperation with both gas and electricity TSOs with regard to all input data. Such data has been reviewed and a dedicated Taskforce set up for quality control. Alongside this, the ENTSOs have completed an alignment survey in order to validate the input data in line with the new framework guidelines and ensuring consistency and alignment to the NECPs and, if deviated, justification has been provided. These steps represent improvements in the process to ensure sector alignment.</p>
6.	<p>Use only one infrastructure level used for the IGI assessment and several for PS-CBA</p> <p>(assessment – point 33).</p>	<p>TYNDP Infrastructure Gaps Identification Report</p> <p>Only three hydrogen projects, namely two storage and one transmission project were declared in TYNDP 2024 as having the start of the construction phase ahead of the project collection. Moreover, environmental impact assessment was not required as part of the project timeline. Therefore, this proposed IGI starting grid would have not been possible to implement in the TYNDP 2024 assessment.</p> <p>Following the ACER recommendation, ENTSOG will request the specified information to project promoters in the upcoming TYNDP 2026 cycle.</p> <p>Depending on the number of projects in the two levels of maturity and in case there exist sufficient interconnected countries, ENTSOG will reassess the choice of the starting grid and may consider to change it, taking into account ACER's indication.</p>

Nr.	ACER long-term recommendations (TYNDP 2024)	Related TYNDP/ENTSOG process
7.	<p>Increase stakeholder engagement, including consider extending of scope of the Stakeholder Reference Group (SRG) to the IGI assessment</p> <p>(ACER opinion – point 4, key findings and recommendations – point 7, assessment – point 26)</p>	<p>TYNDP process – stakeholder engagement</p> <p>Inclusive and extensive stakeholder engagement constitute an essential pillar in the development of ENTSOG’s work, including the TYNDP. In the 2024 cycle, a series of improvements have been done to extend stakeholder engagement and deepen cross-sector modelling:</p> <ul style="list-style-type: none"> • The provisions of the revised TEN-E Regulation were fully applied, amplifying stakeholder engagement and adding extensive consultation requirements to key-phases of the TYNDP process. Five stakeholder consultations have been organised for assumptions, guidance documents, as well as final deliverables, including presentation and discussion events. • In particular for the TYNDP 2024 Scenarios process, the SRG was established in November 2023. The complementing expertise from this balanced group brought improvements to engagement efficiency and effectiveness of Scenarios. • The revised TEN-E added new processes for provision of formal opinions by the EC and ACER, in particular to scenario development, infrastructure gaps identification and the cost-benefit analysis methodology for project assessment. It must be noted that while reinforcing alignment between organisations, these changes also extended the TYNDP process duration. <p>The priority for TYNDP 2026 is to consolidate current collaboration with the SRG and stakeholder engagement in line with the updated TEN-E. In addition, the TYNDP 2026 will involve a new stakeholder: ENNOH.</p> <p>As a final comment, echoing ENTSOG’s 2022 answer to a related request, it is important to underline that in the implementation in each new TYNDP, updates due to feedback from a growing number of stakeholders inevitably affect the overall timeline and introduce additional uncertainty regarding the final publication date. Multiple interactions with stakeholders, as well as potential delays in receiving their responses, further influence the project schedule.</p> <p>In general, the priority for ENTSOG is to ensure, besides through validation of results, that all stakeholders have an opportunity to provide their feedback, while aligning as well as possible with the European Commission’s PCI/PMI process timeline.</p>
8.	<p>Streamline and anticipate the development of the IGI methodology, though early testing</p> <p>(Key findings and recommendations – point 6, Opinion – point 5)</p>	<p>TYNDP process</p> <p>As a general practice, TYNDP simulations are usually run with the most recent available data during a preparation phase. ENTSOG is committed to ensure model readiness as early as possible. Modelling innovations however, might require extensive testing, to confirm results are accurate and trust-worthy.</p> <p>In the TYNDP 2024, the model used for IGI simulations (the DHEM) had been newly developed and therefore required such extensive testing. When a new model is introduced, testing results can either be related to its configurations or to the data inputs. Repeated iterations are usually required to reach an accurate model set-up, cross-check and validate results.</p> <p>In TYNDP 2026, the approach will be maintained. While model improvements will still require testing, with the most recent available data, the robust base from TYNDP 2024 is likely to ensure testing is faster and earlier than in the previous cycle. ENTSOG shall continue informal exchanges with the EC and ACER, where preliminary results are discussed as soon as available and verified.</p>
9.	<p>Implement ACER’s recommendations regarding last-minute data updates to scenarios, as provided in its framework guidelines for the joint TYNDP</p> <p>(assessment – point 28).</p>	<p>TYNDP Scenarios – Data collection and processing</p> <p>As the <u>ACER-commissioned study</u> on the development of scenarios for EU-wide infrastructure planning also finds, there indeed exists a misalignment between the availability of NECP data and the development of the joint TYNDP Scenarios, as well as in the time horizons covered. In addition, the hydrogen market in particular is at an early stage, during which projections are more likely to change, as well as supporting policies.</p> <p>The TYNDP 2024 Scenarios data collection was completed ahead of draft NECP publication, for which the European Commission requested updated hydrogen supply and demand data for the PCI/PMI selection process. While ENTSOG agrees data updates can be necessary in specific cases, we support a standardised, transparent approach, where data is scrutinised by relevant stakeholders.</p> <p>In addition, ENTSOG and ENTSOE adjusted specific country data of the National Trends scenario, so as to respect the energy and climate target compliance. This was done in line with a publicly consulted ‘Gap Closing Methodology’.</p>

3 HYDROGEN INFRASTRUCTURE LEVELS

3.1 PCI/PMI HYDROGEN INFRASTRUCTURE LEVEL

Projects conforming the PCI/PMI hydrogen infrastructure level are shown in the Figure 1 and are listed in Annex I of the TYNDP 2024 Annex D1⁴. The hydrogen production assets available in both hydrogen infrastructure levels are identical and stated in Annex I of this report.

This IGI report focusses the analysis on two assessed simulation years (i.e., 2030 and 2040). Not all projects included in the PCI/PMI hydrogen infrastructure level will be fully implemented in the 2030 timeframe. It might be the case that projects are composed by several phases with different commissioning years and that the commissioning year of some projects and/or phases is 2030 or later and therefore not considered in the 2030 assessment⁵. Whereas, in the 2040 assessment, full deployment of PCIs and PMIs is assumed.

Regarding intra-EU transmission infrastructure, in the PCI/PMI hydrogen infrastructure level, some Southern European countries are not connected to the European network, as visible in Figure 1. More specifically, the Greek and Bulgarian hydrogen systems are interconnected by PCIs, but remain isolated from other neighbouring countries. Countries and regions that are isolated without any cross-border hydrogen infrastructure in this hydrogen infrastructure level are Hungary, Romania, Slovenia, Switzerland, Croatia, Ireland, the United Kingdom, Cyprus, Malta, Luxembourg, the France-Southwest region, the Poland-North-region and the Poland-South region. Slovakia is isolated in 2030 and connected with Czechia and Austria only in 2040.

Regarding storage infrastructure in the PCI/PMI hydrogen infrastructure level, only Denmark, Germany, the Netherlands, France, and Spain have hydrogen storage capacities (see Table 1).

Storage capacities	Direction	2030	2040
Denmark	Injection	3.16	3.16
Denmark	Withdraw	9.5	9.5
Denmark	Working Gas Volume	100	100
France	Injection & Withdraw	10.0	10.0
France	Working Gas Volume	250	250
Germany	Injection & Withdraw	4.25	21.25
Germany	Working Gas Volume	154	359
Netherlands	Injection & Withdraw	3.3	13.2
Netherlands	Working Gas Volume	206	850
Spain	Injection & Withdraw	62.0	62.0
Spain	Working Gas Volume	708	2728
Sum	Injection	82.71	109.61
Sum	Withdraw	89.05	115.95
Sum	Working Gas Volume	1418	4287

Table 1: Hydrogen storage capacities considered in the PCI/PMI hydrogen infrastructure level for the assessed years (unit: GWh/d for injection and withdrawal and GWh for working gas volume).

⁴ Available on <https://tyndp2024.entsog.eu/downloads/>

⁵ Hydrogen infrastructure capacities of the PCI/PMI hydrogen infrastructure level as well as the Advanced hydrogen infrastructure level for 2030 and 2040 are published as part of the TYNDP 2024 Annex C2, available on <https://tyndp2024.entsog.eu/downloads/>

Regarding extra-EU supplies, the PCI/PMI hydrogen infrastructure level has limited access to extra-EU supply potential. This is particularly relevant when considering the 2030 assessment:

- Regarding pipeline imports from extra-EU sources (see Table 2): PCIs and PMIs are considered to unlock North African, Norwegian and Ukrainian supply potential only from 2040.

- Regarding hydrogen import terminals (see Table 3): In 2030, extra-EU imports will be limited to the PCI import terminals in Belgium, Germany, and the Netherlands. In 2040, higher capacity of PCI import terminals will be considered in these countries due to the planned full implementation of the multiple phases of the PCIs. In 2040, also an additional PCI import terminal located in France will be considered to be connected to the Belgian hydrogen network.

From Country	To Country	Hydrogen import capacity		Extra-EU hydrogen supply potential		Effective hydrogen import potential	
		2030	2040	2030	2040	2030	2040
Algeria	Italy	0.0	448.0	116.8	1,124.5	0.0	448.0
Morocco	Spain	0.0	106.0	0.0	106.2	0.0	106.0
Norway	Germany	0.0	432.0	146.3	724.52	0.0	432.0
Ukraine	Slovakia	0.0	218.4	85.0	878.9	0.0	218.4

Table 2: Extra-EU import capacities via pipelines considered in the PCI/PMI hydrogen infrastructure level and extra-EU supply potential for the assessed years (unit: GWh/d).

Import capacities by ship To Country	2030	2040
Belgium	59.3	193.6
France	0.0	48.0
Germany	44.2	67.7
The Netherlands	90.8	177.1
Sum	194.3	486.4
Shipped supply potential	2030	2040
Extra-EU to EU	193.3	1,327.4
Effective hydrogen import potential	2030	2040
Minimum of import capacities by ship and shipped supply potential	194.3	486.4

Table 3: Extra-EU import capacities via terminals considered in the PCI/PMI hydrogen infrastructure level and extra-EU supply potential by ship for the assessed years (unit: GWh/d).

KEYS

ENTSO-G currently comprises 43 TSO members, 1 Associated Partner and 9 Observers from 32 European Countries

When the same point is affected by several projects, the point is shown with the highest project status (operational, FID, advanced, non-FID) the status from single projects carry over from that. The projects are shown with their planning status reported in their TNDP 2024 submissions.

Project information, initially based on TNDP project collection conducted in Nov 2023 - Feb 2024.

All data provided on this map is for information purposes and shall be treated as indicative and non-contractual in nature, without pre-empting different outcomes of any possible discussion held at regional level. Under no circumstances shall it be regarded as information intended for commercial use.

Project status:

Infrastructure Project Name	ENTSO-G code / color	Project status codes
Project ENTSG code	Project Name	Project Promoter
Project not marked on map	Exact project location is not available or is marked as confidential	Project is part of 1 st PCP/PM list
Exact project location is not available or is marked as confidential	Project has several locations/points	Project is not part of 1 st PCP/PM list
The indicated location is for information purposes only and does not indicate the exact location of the project	Needs added context in TNDP 2024 (additional to www.entso-g.eu)	

Project status codes:
The project advancement status is based on the TNDP project collection conducted in Nov 2023 - Feb 2024.

Advanced	Non-Advanced	PCJ status (Project of Common Interest)
FID	Advanced	FID status (Final Investment Decision)

Advanced status is applied to all projects that, based on the information submitted, have Commissioning requested at the latest by 31 December 2029 AND the project fulfils at least one of the following criteria:

- Project has taken the final investment decision (FID) ahead of the TNDP 2024 project collection
- Project is included in the NRP(s) of the respective country(ies) or in the national law
- Project has successfully consulted the market through a market test (including non-binding processes), which achieved positive results

Cross-border points / Intra-country or intra balancing zone points

- Cross-border interconnection point within Europe or beyond point to non EU country
- Cross-border interconnection point with third country (3CPT)
- LNG import terminal (operational)
- Intra country or intra balancing zone points
- Cross-border interconnection point (Visual Data)

Transport by pipeline

- Existing infrastructure for natural gas: Diameter < 600 mm, Diameter 600 - 900 mm, Diameter > 900 mm
- Planned infrastructure for natural gas: Project

Storage facilities

- Acquirer
- Salt cavity - cavern
- Depleted Gas field on shore / offshore
- Other type
- Gas storage projects

Gas Reserve areas

- Gas field
- Drilling platform
- EU Countries
- Other Countries

Hydrogen Transmission Pipelines (H2T)

Project is part of 1st PCP/PM list:

- FID projects
- Non-FID, advanced projects
- Non-FID, less advanced projects

Project identification:

- ENTSG project code

Hydrogen Storage Facilities (H2S)

Project is part of 1st PCP/PM list:

- FID projects
- Non-FID, advanced projects
- Non-FID, less advanced projects

Project identification:

- ENTSG project code

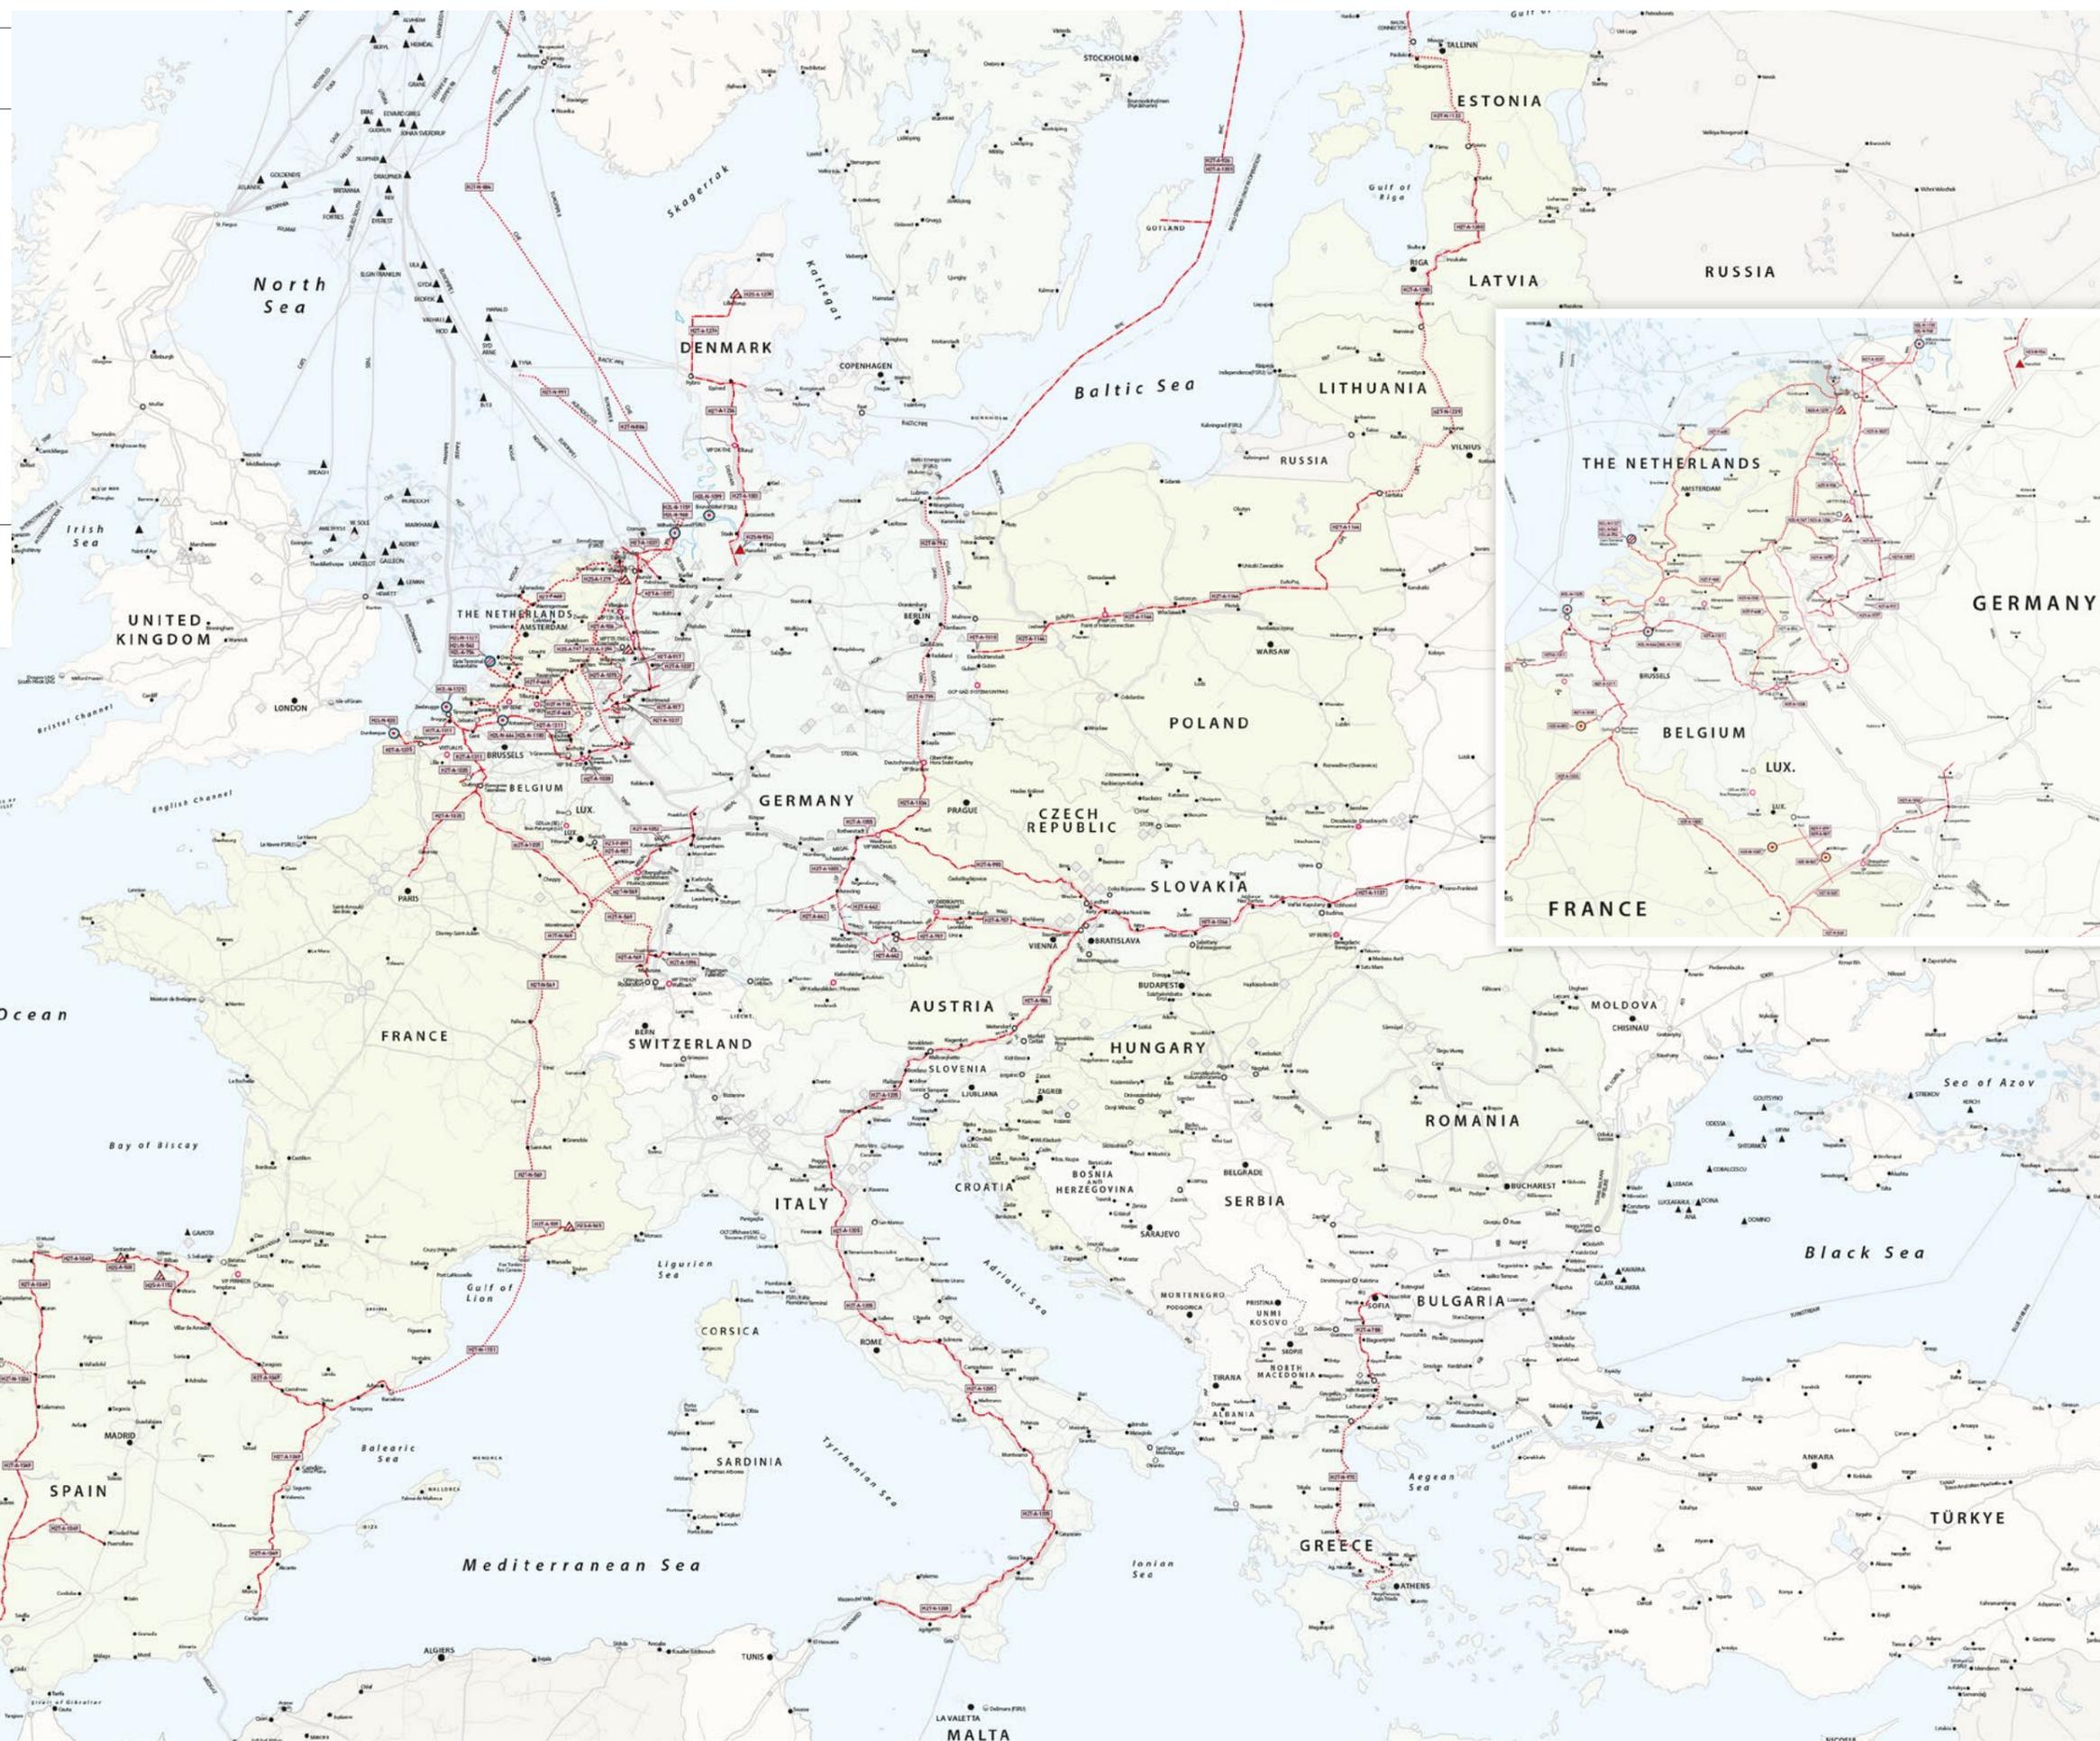

Hydrogen Reception Facilities (H2R)

Project is part of 1st PCP/PM list:

- FID projects
- Non-FID, advanced projects
- Non-FID, less advanced projects

Project identification:

- ENTSG project code

3.2 ADVANCED HYDROGEN INFRASTRUCTURE LEVEL

The Advanced hydrogen infrastructure level is by definition more ambitious than the PCI/PMI hydrogen infrastructure level, as it contains not only the PCIs and PMIs, but also advanced hydrogen projects, which can involve countries without PCIs and PMIs.

Projects conforming the Advanced hydrogen infrastructure level are shown in the map in Figure 2 and are listed in Annex I of the TYNDP 2024 Annex D1. The hydrogen production assets available in both hydrogen infrastructure levels are identical and stated in Annex I of this report.

Regarding intra-EU transmission infrastructure, the Advanced hydrogen infrastructure level has a higher

level of interconnections in Southern Europe, as visible in Figure 2. More specifically, Slovakia, Hungary, Romania, Croatia and Bosnia are interconnected in the Advanced hydrogen infrastructure level. Countries and regions that are isolated without any cross-border hydrogen infrastructure in this hydrogen infrastructure level are Luxembourg, Slovenia, Switzerland, Ireland, the United Kingdom, Cyprus, Malta, the France-Southwest region⁶, the Poland-North and the Poland-South region.

Regarding storage infrastructure, the Advanced hydrogen infrastructure level has higher storage capacities in Germany and in the France-Southwest region (see Table 4).

Storage capacities	Direction	2030	2040
Denmark	Injection	3.16	3.16
Denmark	Withdraw	9.5	9.5
Denmark	Working Gas Volume	100	100
France ⁷	Injection & Withdraw	19.3	19.3
France	Working Gas Volume	750	750
Germany	Injection & Withdraw	63.25	80.25
Germany	Working Gas Volume	1,532	1,737
Netherlands	Injection & Withdraw	3.3	13.2
Netherlands	Working Gas Volume	206	850
Spain	Injection & Withdraw	62.0	62.0
Spain	Working Gas Volume	708	2728
Sum	Injection	151.01	173.91
Sum	Withdraw	157.35	184.25
Sum	Working Gas Volume	3,296	6,165

Table 4: Hydrogen storage capacities considered in the Advanced hydrogen infrastructure level for the assessed years (units: GWh/d for injection and withdrawal and GWh for working gas volume).

⁶ The hydrogen southwest region would not be isolated if MidHY was considered at the same maturity status as the rest of the projects in this geographical area. The results should show that, from 2030, the MidHY project would ensure, with the HySoW project, the export of significant excess volumes of Renewable and Low Carbon hydrogen from the south west zone of France to the HI west corridor.

⁷ Some storage capacity in France is connected to the France-South region and some is connected to the France-Southwest region.

Regarding extra-EU supplies, the Advanced hydrogen infrastructure level has additional access to extra-EU supply potential compared to the PCI/PMI hydrogen infrastructure level:

- Regarding pipeline imports from extra-EU sources (see Table 5): The Advanced hydrogen infrastructure level includes access to North African (Algerian and Tunisian) supply in 2030 thanks to a project connecting Italy with this import source.

- Regarding hydrogen import terminals (see Table 6): The Advanced hydrogen infrastructure level has higher import capacity in the Netherlands and in Poland due to the inclusion of advanced hydrogen import terminals.

From Country	To Country	Hydrogen import capacity		Extra-EU hydrogen supply potential		Effective hydrogen import potential	
		2030	2040	2030	2040	2030	2040
Algeria	Italy	448.0	448.0	116.8	1,124.5	116.8	448.0
Morocco	Spain	0.0	106.0	0.0	106.2	0.0	106.0
Norway	Germany	0.0	432.0	146.3	724.52	0.0	432.0
Ukraine	Slovakia	0.0	218.4	85.0	878.9	0.0	218.4

Table 5: Extra-EU import capacities via pipelines considered in the Advanced hydrogen infrastructure level and extra-EU supply potential for the assessed years (unit: GWh/d).

Import capacities by ship to Country	2030	2040
Belgium	59.3	193.6
France	0.0	48.0
Germany	44.2	67.7
The Netherlands	136.3	222.6
Poland	17.7	17.7
Sum	257.5	549.6
Shipped supply potential	2030	2040
Extra-EU to EU	193.3	1327.4
Effective hydrogen import potential	2030	2040
Minimum of import capacities by ship and shipped supply potential	227.8	549.6

Table 6: Extra-EU import capacities via terminals considered in the advanced hydrogen infrastructure level and extra-EU supply potential by ship for the assessed years (unit: GWh/d).

- Project is part of 1+ PC/PM list

4 INFRASTRUCTURE GAPS IDENTIFICATION (IGI) INDICATORS

The analysis is performed for 2030 and 2040 as simulation years for the TYNDP 2024 National Trends+ scenario. It covers both hydrogen infrastructure levels. Thereby, three indicators are used to identify regional hydrogen infrastructure gaps. IGI indicator 1 and IGI indicator 2.1 thereby use a reference weather year (i.e., 1995), while IGI indicator 2.2 uses a stressful weather year (i.e., 2009). The application of these IGI indicators is explained in the following paragraphs. Additional justifications and examples are available in section 5 of TYNDP 2024 Annex D2.

The IGI indicators identify the existence of an infrastructure gap through the existence of effects of such infrastructure gap. The non-identification of a certain infrastructure gap may be related to the infrastructure considered in the infrastructure levels of the energy sectors considered in the models. The effect of this infrastructure gap is either expressed at a border for IGI indicator 1 (see section 4.1) or at a country for IGI indicators 2.1 and 2.2 (see section 4.2 and section 4.3).

The reason for an infrastructure gap is an infrastructure bottleneck. An infrastructure bottleneck is a physical congestion of the network that can be observed based on full utilization rates of all relevant transmission infrastructure during certain periods of time. As a limited cooperation mode is used among countries in situations of hydrogen scarcity (see section 3.2.4 of the TYNDP 2024 Annex D1), the dominant infrastructure bottleneck is not necessarily located at a border of the country through which the IGI indicators demonstrated the existence of an infrastructure gap (see examples in section 5 of TYNDP 2024 Annex D2).

Also, besides the dominant bottleneck, non-dominant bottlenecks may exist at other locations that only unfold their effect once the dominant bottleneck is addressed. Additionally, an infrastructure bottleneck can in principle be solved by different projects and via different routes. Therefore, the infrastructure gaps identified by the IGI indicators identify regional infrastructure gaps, as the potential solution to it is not limited to the border of IGI indicator 1 or the country of IGI indicator 2. Potential solutions may in principle involve import projects, production projects, transmission projects, and storage projects.

4.1 IGI INDICATOR 1: HYDROGEN MARKET CLEARING PRICE SPREADS IN DHEM

This IGI indicator aims at identifying hydrogen infrastructure gaps by assessing Zone 2 nodes of different countries based on differences in hydrogen market clearing prices between these nodes. Zone 2 nodes are areas of hydrogen production and/or storage and/or consumption within a country that are considered to be connected to the national hydrogen backbone. The hydrogen market clearing price spread is thereby based on the hourly hydrogen market clearing prices in the DHEM simulations. It is calculated for each combination of simulation year and hydrogen infrastructure level.

The hydrogen prices and flows in the DHEM are linked to the merit order of hydrogen supply options as well as hydrogen demand associated with end users' willingness to pay for hydrogen (i.e., WTP_{H_2} as defined in TYNDP 2024 Annex D1). The merit order of hydrogen production has the following elements:

- ▲ **Hydrogen imports** have specific costs as defined in the TYNDP 2024 NT+ scenario;
- ▲ **Electrolytic hydrogen production** costs are linked to the price of the used electricity and the water price in the respective country as well as the process efficiency;
- ▲ **Hydrogen production from natural gas** within the EU is based on the TYNDP 2024 NT+ scenario and depends on the natural gas price, operating and maintenance costs, process efficiency, and Emissions Trading System (ETS) costs (thereby being differentiated between low-carbon and unabated hydrogen production from natural gas).

Especially the electrolytic hydrogen production thereby depends on the availability of RES and nuclear energy. Electrolysers that are connected to an electricity bidding zone or dedicated RES may be limited in their load factor by this availability. Also, the electricity price is subject to a merit order of electricity production as well as the end users' willingness to pay for electricity (e.g., VoLL). The electricity price is thereby influencing the cost of electrolytic hydrogen production.

As the DHEM aims at maximising the joint market rents in the electricity sector and in the hydrogen sector, it dispatches the European electricity and hydrogen supply options in an optimised way while respecting hard constraints like production and transport capacities. Thereby, the most expensive hydrogen supply source is usually defining the hydrogen market clearing price in a perfectly interconnected area. However, in case of hydrogen undersupply, the end users are competing for this supply up to their willingness to pay for hydrogen, thereby setting the hydrogen market clearing price at this level. From this dispatch of production options result hydrogen (and electricity) flows.

If countries are well connected, they share the same hydrogen market clearing price. If countries are not connected at all, the interdependency of their hydrogen market clearing prices is limited as these prices then depend on their own hydrogen supply options and hydrogen demand. A certain correlation may still be observed, e.g., due to one or several of the following reasons:

- ▲ The price and availability of electricity used for electrolytic hydrogen production may be correlated (e.g., due to similar weather conditions in these countries and/or sufficient cross-border capacity in the electricity system).
- ▲ The reliance on the same means of hydrogen production from natural gas may be correlated.
- ▲ The frequency of hydrogen demand curtailment may be correlated.

When countries are connected but the sum of connections between them is a bottleneck during certain periods of time, the hydrogen market clearing price is the same during periods of time when the interconnection is not acting as a bottleneck and is detached when the interconnection is acting as a bottleneck. Then, a limited price correlation can be observed. The less often the bottleneck is observed and the lower the resulting price spread during these periods of detachment is, the lower is the average price spread.

To define which hydrogen market clearing price spreads are a significant indication of a hydrogen infrastructure gap, one of the following thresholds must be passed:

▲ **Threshold 1:** This refers to a hydrogen market clearing price difference. It is calculated as the yearly average of the absolute hourly price differences between two Zone 2 nodes. The threshold is exceeded if this average difference is greater than 4 €/MWh.

▲ **Threshold 2:** A hydrogen market clearing price spread as the absolute average daily hydrogen market clearing price spread between two Zone 2 nodes of different countries of more than 20 €/MWh for more than 40 days per year.

If there is a hydrogen market clearing price spread above one of the thresholds, this indicates an infrastructure gap for the given assumptions.

More details are provided by TYNDP 2024 Annex D1 and TYNDP 2024 Annex D2.

4.2 IGI INDICATOR 2.1: CURTAILED HYDROGEN DEMAND IN DHEM AND DGM FOR REFERENCE WEATHER YEAR

This IGI indicator identifies infrastructure gaps by measuring the hydrogen demand curtailments of individual nodes during the reference weather year (i.e., 1995), and without infrastructure or source disruptions. The following simulation logic is applied for each combination of simulation year and hydrogen infrastructure level:

1. A DHEM simulation is run with the reference weather year data (i.e., the same simulation is used for IGI indicator 1).
2. Certain DHEM outputs from step 1 that influence the natural gas demand, hydrogen production, and hydrogen consumption are transferred into the DGM (see sections 2.4.5 and 2.4.6 of the TYNDP 2024 Annex D1).
3. A DGM simulation is run on the basis of step 2.
4. Per node, the combined hydrogen demand curtailment from the DHEM simulation and the additional hydrogen demand curtailment from the DGM are provided.

To define which hydrogen demand curtailments are a significant indication of a hydrogen infrastructure gap, the following threshold must be passed:

▲ **Threshold:** A yearly average hydrogen demand curtailment rate of more than 0 %.

If there is a hydrogen demand curtailment above the threshold, this indicates an infrastructure gap for the given assumptions.

In this draft TYNDP 2024 IGI report, the IGI indicator 2.1 is only based on the hydrogen demand curtailment from the DHEM simulations.

4.3 IGI INDICATOR 2.2: CURTAILED HYDROGEN DEMAND IN DHEM AND DGM FOR STRESSFUL WEATHER YEAR

This IGI indicator identifies infrastructure gaps by measuring the hydrogen demand curtailments of individual nodes under stressful weather conditions (i.e., 2009).

The following simulation logic is applied for each combination of simulation year and hydrogen infrastructure level:

1. A DHEM simulation is run with the stressful weather year data.
2. The DHEM outputs from step 1 that influence the natural gas demand, hydrogen production, and hydrogen consumption are transferred into the DGM (see sections 2.4.5 and 2.4.6 of the TYNDP 2024 Annex D1).
3. A DGM simulation is run on the basis of step 2.
4. Per node, the combined hydrogen demand curtailment from the DHEM simulation and the additional hydrogen demand curtailment from the DGM are provided.

To define which hydrogen demand curtailments are a significant indication of a hydrogen infrastructure gap, one of the following thresholds must be passed:

- ▲ **Threshold 1:** A yearly average hydrogen demand curtailment rate of more than 3 %.
- ▲ **Threshold 2:** A hydrogen demand curtailment rate of more than 5 % for at least one calendar month per year.

If there is a hydrogen demand curtailment above one of the thresholds, this indicates an infrastructure gap for the given assumptions.

In this draft TYNDP 2024 IGI report, the IGI indicator 2.2 is only based on the hydrogen demand curtailment from the DHEM simulations.

5 DISCLAIMERS

The results of the TYNDP 2024 IGI report are only related to infrastructure gaps that are based on the considered infrastructure levels. Therefore, the TYNDP 2024 IGI report cannot find that an infrastructure that is part of the smallest considered infrastructure level (i.e., the PCI/PMI hydrogen infrastructure level) is not addressing any infrastructure gap. Therefore, all the projects constituting the PCI/PMI hydrogen infrastructure level are to be treated as equally and jointly necessary for addressing the infrastructure gaps considered in the analysis.

The results of the TYNDP 2024 IGI report are related to the assessed scenario (i.e., NT+) and years (i.e., 2030 and 2040).

The lines depicted in the grid flow maps are derived from simulations used to identify infrastructure gaps within the assessed infrastructure levels and assessed years. These indicative lines do not reflect ENTSOG's expectations on how the European network will evolve during the simulated years. The report's primary objective is to identify gaps, not to predict the development of European infrastructure neither the future flows. Additionally, many projects included in the TYNDP are not part of the analysed infrastructure levels.

Their commissioning could complement network flows compared to those presented in the report and potentially address some of the identified infrastructure gaps.

The term “*bottleneck*” in this report refers to situations where two conditions are met: (1) the capacity is being utilized to its maximum potential, and (2) no alternative routes are available. When a capacity is identified as a bottleneck, it signals the need for potential enhancements to that capacity at the specific fully utilized route and/or the development of new projects following other interconnections.

No generic hydrogen infrastructure projects are used in this TYNDP 2024 IGI report. Instead, only real projects that were submitted by project promoters are considered.

The representation of grid flows in the maps of this report is based on a schematic representation from capital to capital.

All values that refer to the energy content of molecules (e.g., GWh/d, €/MWh or TWh/y) are stated in terms of their Gross Calorific Value (GCV) in this IGI report. For hydrogen, the conversion factor from NCV to GCV is 1.176.

6 ASSESSMENT FOR 2030

This section describes the evolution of the IGI indicators for the reference weather year (i.e., 1995) and the stressful weather year (i.e., 2009) for the analysed infrastructure levels (i.e., PCI/PMI and Advanced hydrogen infrastructure levels) for the simulation year 2030.

6.1 INFRASTRUCTURE GAPS IDENTIFICATION

In 2030, the PCI/PMI hydrogen infrastructure level's extra-EU imports are limited to shipped imports through the PCI reception terminals in Belgium, Germany and the Netherlands. The overall contribution of shipped hydrogen imports are rather limited when compared to the overall EU hydrogen demand. Therefore, in this infrastructure level, European hydrogen demand is mostly met by indigenous production through electrolysis or hydrogen

production using natural gas which are not enough to fully cover the hydrogen demand. Therefore, curtailed hydrogen demand is significant.

In 2030, in the Advanced hydrogen infrastructure level, Europe will receive imports also from North Africa contributing to the reduction of hydrogen demand curtailment via higher utilisation rates of interconnected supply corridors.

6.1.1 ASSESSMENT OF PCI/PMI HYDROGEN INFRASTRUCTURE LEVEL

High-level results for reference weather year

The overall yearly supply-demand balance for the PCI/PMI hydrogen infrastructure level in 2030 for the reference weather year is presented in Table 7. As detailed in Table 7, electrolytic hydrogen pro-

duction is the main source of hydrogen in Europe. This assessment results in an approximate share of 8.3 % of hydrogen demand curtailment in Europe.

Yearly hydrogen supply-demand balance	PCI/PMI IL
H ₂ produced via electrolysis	310
H ₂ produced using natural gas	229
H ₂ shipped imports	29
H ₂ pipeline imports	0
Curtailed H ₂ demand	52
H ₂ demand for power production	2
Total H₂ demand	620

Table 7: Supply and demand balance in the PCI/PMI hydrogen infrastructure level in 2030 for reference weather year (unit: TWh/y).

Figure 3 shows the hydrogen production via electrolysis in the different European countries for the PCI/PMI hydrogen infrastructure level in the 2030 assessment. The countries with highest electrolytic hydrogen production are Spain, Finland, Sweden, and Germany. Some countries have more than one source of electrolytic hydrogen production.

This is related to the intra-country assumptions, which can be summarized as it follows:

- ▲ Consideration of electrolytic hydrogen production from dedicated RES in Spain.

- ▲ Consideration of dedicated electrolytic production to satisfy regional hydrogen demand within the country (i.e., Zone 1). This is the case for Austria, Spain, Finland, Croatia, Ireland, Sweden, Slovenia, and the United Kingdom.
- ▲ Consideration of multiple production sub-zones within the main system of a country to reflect different geographical production areas and/or demand areas and/or storage areas stemming from internal transport bottlenecks. This is the case for Denmark, Italy, France, Finland, Sweden, and the United Kingdom.

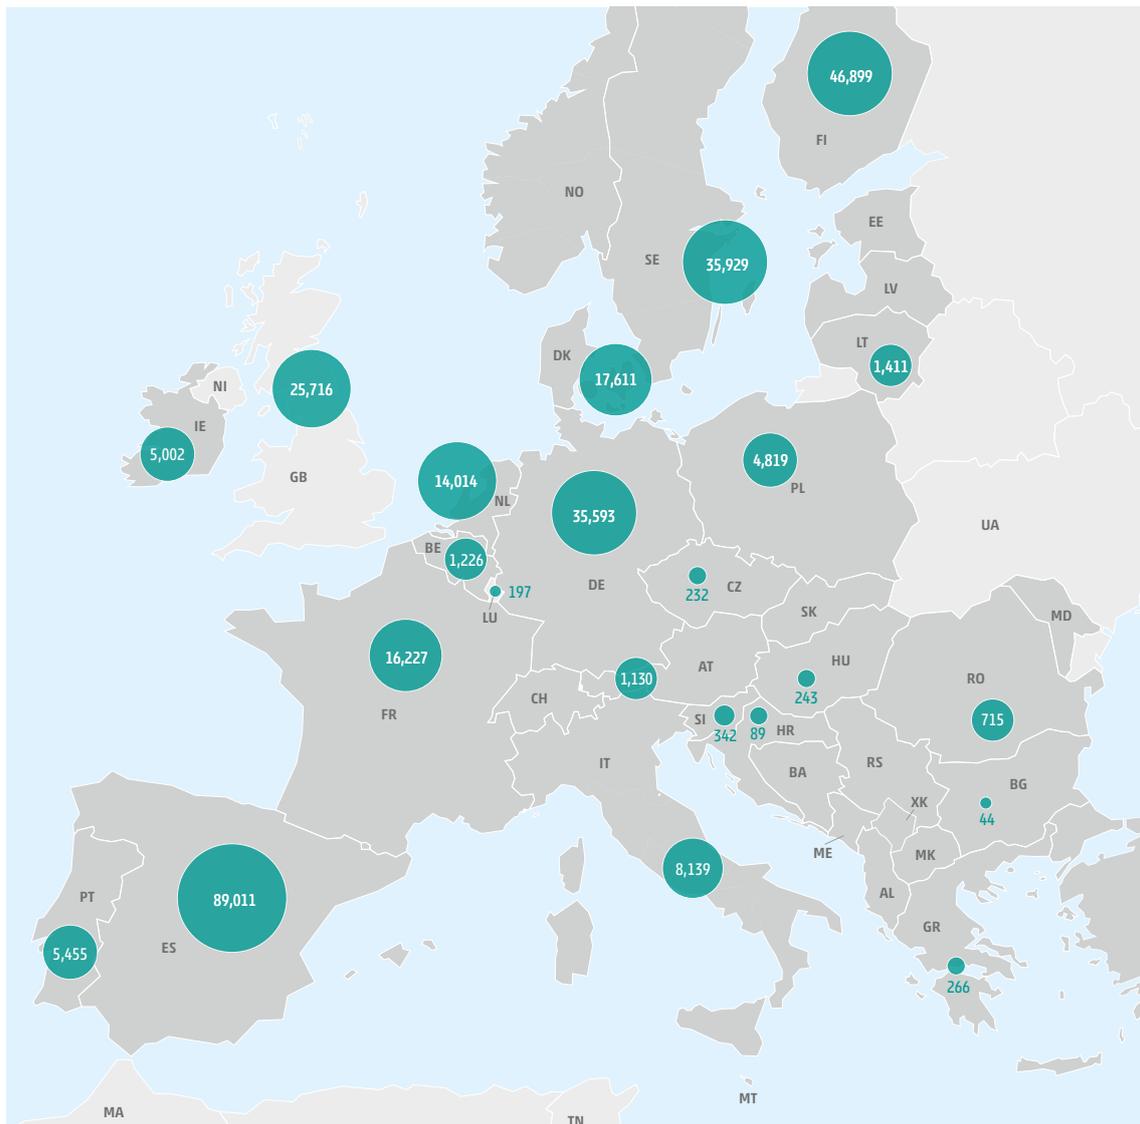

Figure 3: Distribution of hydrogen production via electrolysis in the PCI/PMI hydrogen infrastructure level in 2030 for reference weather year (unit: GWh/y).

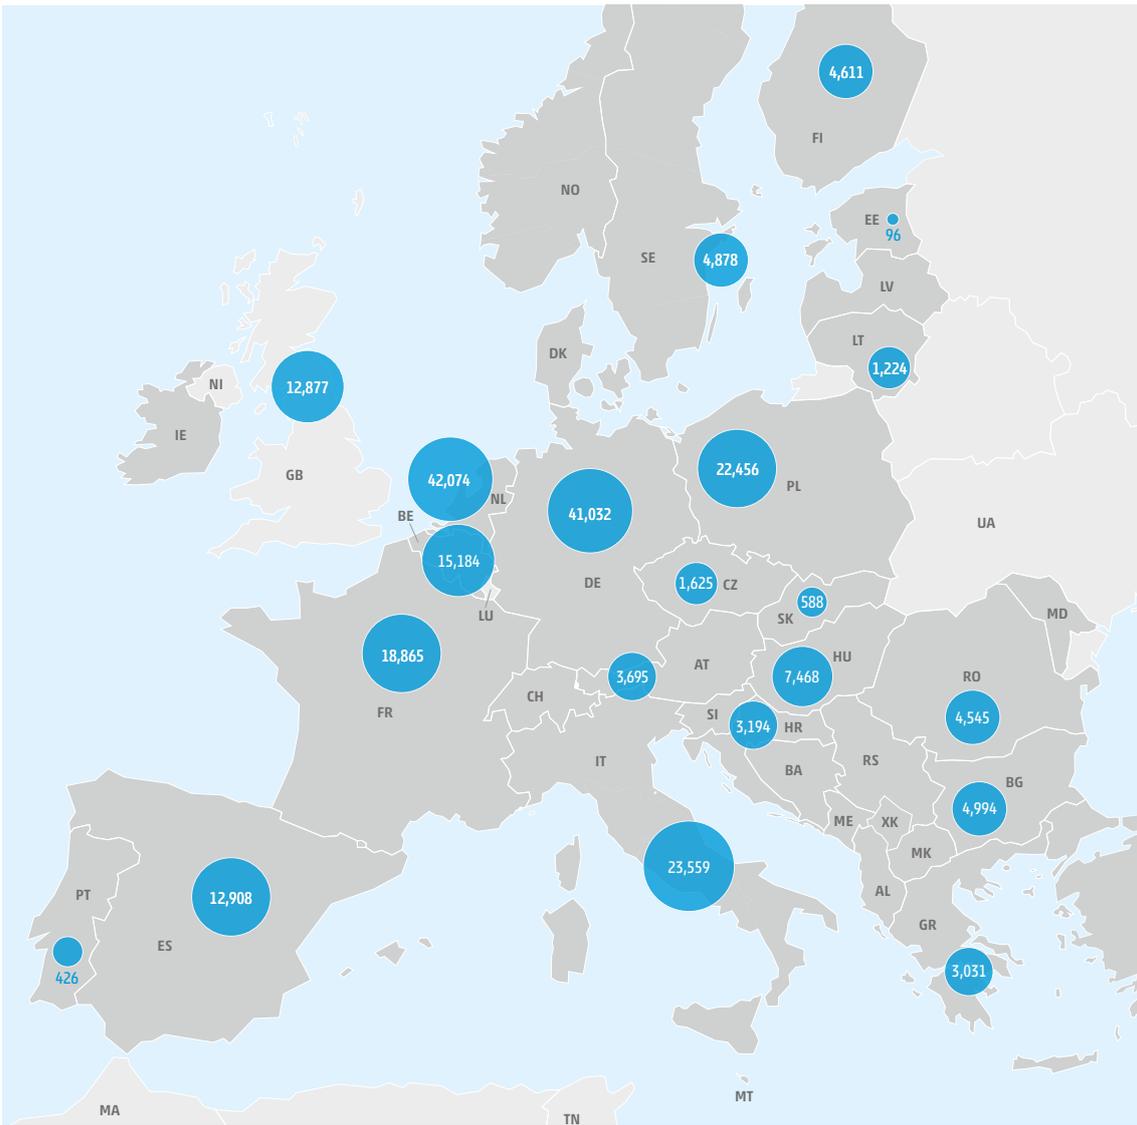

Figure 4: Distribution of hydrogen production from natural gas in the PCI/PMI hydrogen infrastructure level in 2030 for reference weather year (unit: GWh/y).

Table 8: Distribution of hydrogen production, demand and hydrogen imports per country in the PCI/PMI hydrogen infrastructure level in 2030 for reference weather year (unit: GWh/y).

Intra-EU cross-border flows emerge between different European countries due to limitations of available supplies and associated costs. Figure 5 shows these flows.

Two main transport corridors emerge in the PCI/PMI hydrogen infrastructure level in the 2030 assessment, one from the Iberian Peninsula towards Germany through France and one from Nordic countries to Germany.

This result is explained by the fact that these corridors are connecting countries with high availability of supply with other countries where hydrogen supplies might be limited or more expensive.

In addition, among the interconnected countries within the PCI/PMI hydrogen infrastructure level, Germany shows the highest demand and at the same time enables transport of supply to its neighbouring countries, acting as a hydrogen hub.

Figure 5: Grid flows* in the PCI/PMI hydrogen infrastructure level in 2030 for reference weather year (unit: GWh/y).

* Grid flows refer to simulations results and do not intend to represent how the European infrastructure is expected to evolve in the simulated years, being just outcomes of a modelling tool. The values are provided as a table in Annex II and as monthly values in Annex III.

In the 2030 PCI/PMI hydrogen infrastructure level assessment for the reference weather year, countries can be grouped in four different categories according to their supply-demand balance on a yearly basis:

- 1. Countries that export more than they import:** Sweden, Finland, Denmark, Italy, Spain, Portugal and Bulgaria.
- 2. Countries that import more than they export:** Belgium, Poland, Czechia, Greece, Lithuania.
- 3. Transit countries that import more than they consume:** Germany, Austria, France, Belgium, The Netherlands, Estonia, Latvia and Lithuania.

4. Isolated countries: the United Kingdom, Ireland, Luxembourg, Hungary, Romania, Slovakia, Slovenia, Croatia, Malta, Cyprus, Switzerland⁸ and the cluster Bulgaria-Greece.

While on a yearly basis some countries are net exporters and some countries are net importers, net exporters may be relying on net imports during certain shorter periods of time and net importers may be providing net exports during certain shorter periods of time. This can result in bidirectional flows at interconnections. This situation is caused by the seasonality of electrolytic hydrogen production and to some extent by the seasonality of hydrogen demand.

High-level results for stressful weather year

The overall yearly supply-demand balance for the PCI/PMI hydrogen infrastructure level in 2030 for the stressful weather year is presented in Table 9. As detailed in Table 9, electrolytic hydrogen production is the main source of hydrogen in Europe but it is reduced in comparison with the reference

weather year. This assessment results in an approximate share of 11.1 % of curtailed hydrogen demand at European level. This represents an increase by 3 percentage points in comparison with the reference weather year.

Yearly hydrogen supply-demand balance	PCI/PMI IL
H ₂ produced via electrolysis	270
H ₂ produced using natural gas	245
H ₂ shipped imports	36
H ₂ pipeline imports	0
Curtailed H ₂ demand	69
H ₂ demand for power production	2
Total H₂ demand	619

Table 9: Supply and demand balance in the PCI/PMI hydrogen infrastructure level in 2030 for stressful weather year (unit: TWh/y).

Figure 6 shows the hydrogen production via electrolysis in the different European countries for the PCI/PMI hydrogen infrastructure level in the 2030 assessment. The countries with highest electrolytic hydrogen production are Spain, Finland, Sweden, and Germany.

Some countries have more than one source of electrolytic hydrogen production. This is related to the intra-country assumptions, which is explained in section 6.1.1.

⁸ IGI report does not consider hydrogen demand in Switzerland (based on TYNDP 2024 Draft Scenario report). However, there is no hydrogen infrastructure connecting Switzerland to any of its European neighbouring countries in the assessed infrastructure levels.

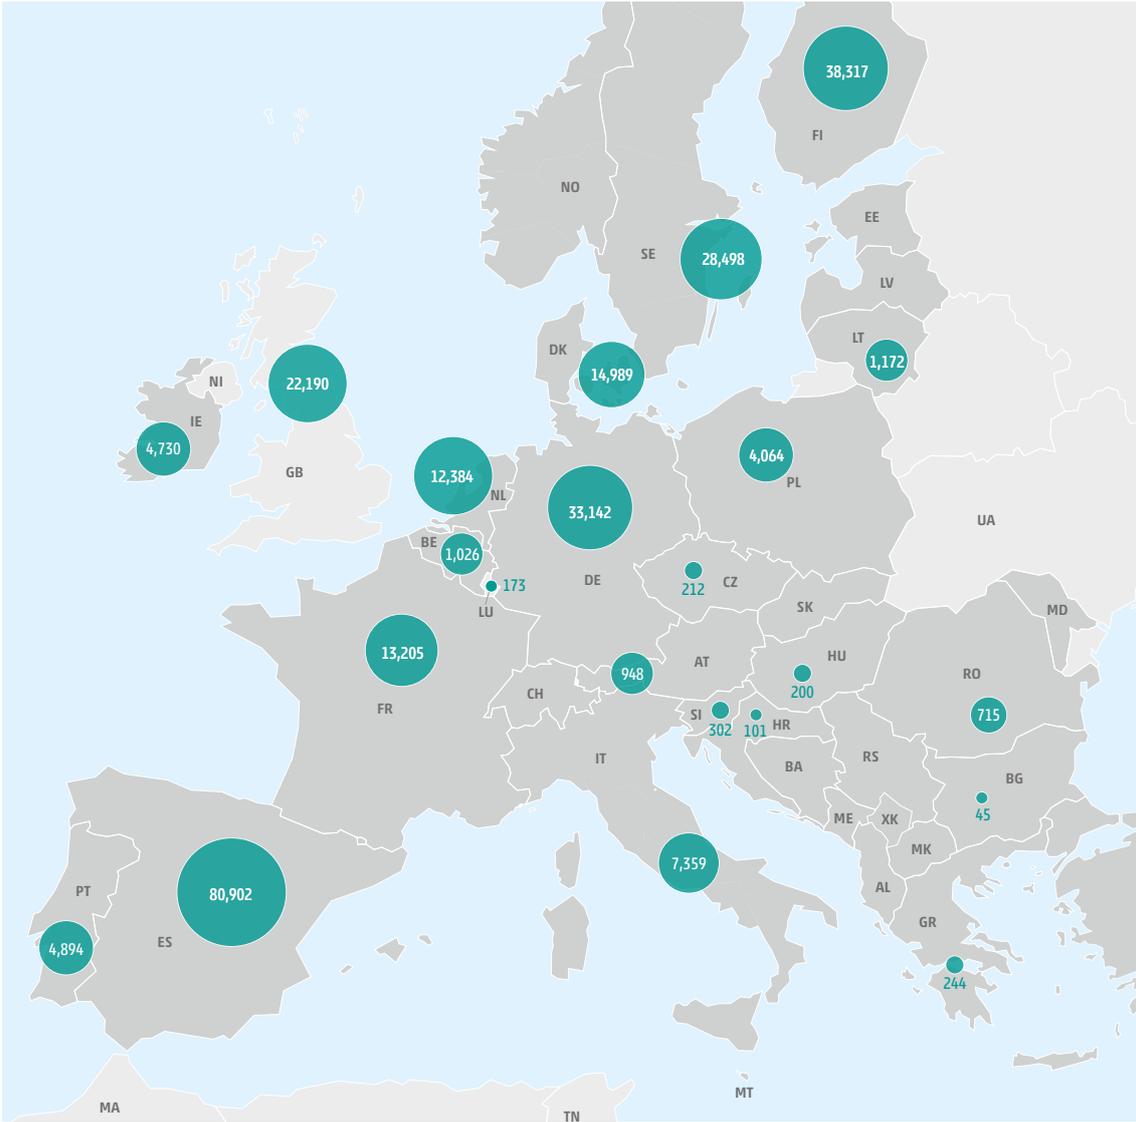

Figure 6: Distribution of hydrogen production via electrolysis in the PCI/PMI hydrogen infrastructure level in 2030 for stressful weather year (unit: GWh/y).

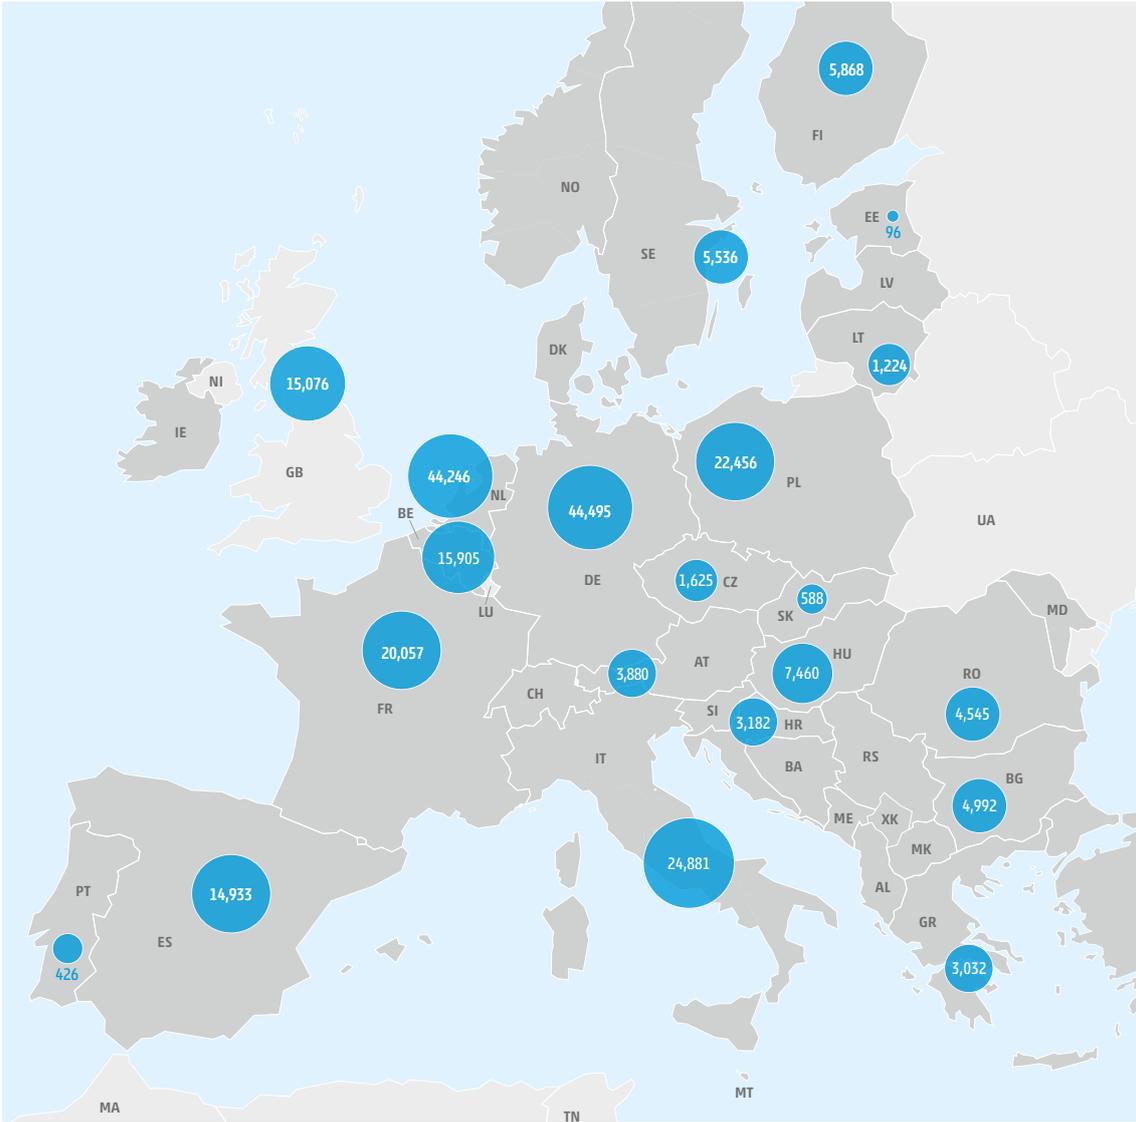

Figure 7: Distribution of hydrogen production from natural gas in the PCI/PMI hydrogen infrastructure level in 2030 for stressful weather year (unit: GWh/y).

Table 10: Distribution of hydrogen production per country in the PCI/PMI hydrogen infrastructure level in 2030 for stressful weather year (unit: GWh/y).

Intra-European cross-border flows emerge between different European countries due to limitations of available supplies and associated costs. Figure 8 shows resulting yearly average flows under stressful weather conditions.

In comparison with the reference weather year, the export from countries that to a large extent base their hydrogen production on RES is reduced. This reduces the usage of the Iberian and of the

Nordic corridor. At the same time, the import terminals must be used to a higher extent, increasing exports of countries and regions with such terminals. Germany maintains its role as hydrogen hub. Despite the overall reduction of electrolytic hydrogen production, under stressful weather conditions the countries with the highest electrolytic hydrogen production follow the same distribution as in the PCI/PMI hydrogen infrastructure level in 2030 for the reference weather year.

Figure 8: Grid flows* in the PCI/PMI hydrogen infrastructure level in 2030 for stressful weather year (unit: GWh/y).

* Grid flows refer to simulation results and don't intend to represent how the European infrastructure is expected to evolve in the simulated years, being just outcomes of a modelling tool. The values are provided as a table in Annex II and as monthly values in Annex III).

In the 2030 PCI/PMI hydrogen infrastructure level assessment for the stressful weather year, countries can be grouped in four different categories according to their supply-demand balance on a yearly basis:

- 1. Countries that export more than they import:** Sweden, Finland, Denmark, Italy, Spain, Portugal.
- 2. Countries that import more than they export:** Poland, Czechia, Greece, Lithuania.

3. Transit countries that import more than they consume: Germany, Austria, France, Belgium, The Netherlands, Estonia, Latvia, and Lithuania.

4. Isolated countries: the United Kingdom, Ireland, Luxembourg, Hungary, Romania, Slovakia, Slovenia, Croatia, Malta, Cyprus, Switzerland⁹ and the cluster Bulgaria-Greece.

⁹ IGI report does not consider hydrogen demand in Switzerland (based on TYNDP 2024 Draft Scenario report). However, there is no hydrogen infrastructure connecting Switzerland to any of its European neighbouring countries in the assessed infrastructure levels.

While on a yearly basis some countries are net exporters and some countries are net importers, net exporters may be relying on net imports during certain shorter periods of time and net importers may be providing net exports during certain shorter

periods of time. This can result in bidirectional flows at interconnections. This situation is caused by the seasonality of electrolytic hydrogen production and to some extent by the seasonality of hydrogen demand.

6.1.1.1 IGI INDICATOR 1: HYDROGEN MARKET CLEARING PRICE SPREADS FOR REFERENCE WEATHER YEAR

Overview: Hydrogen market clearing prices per country

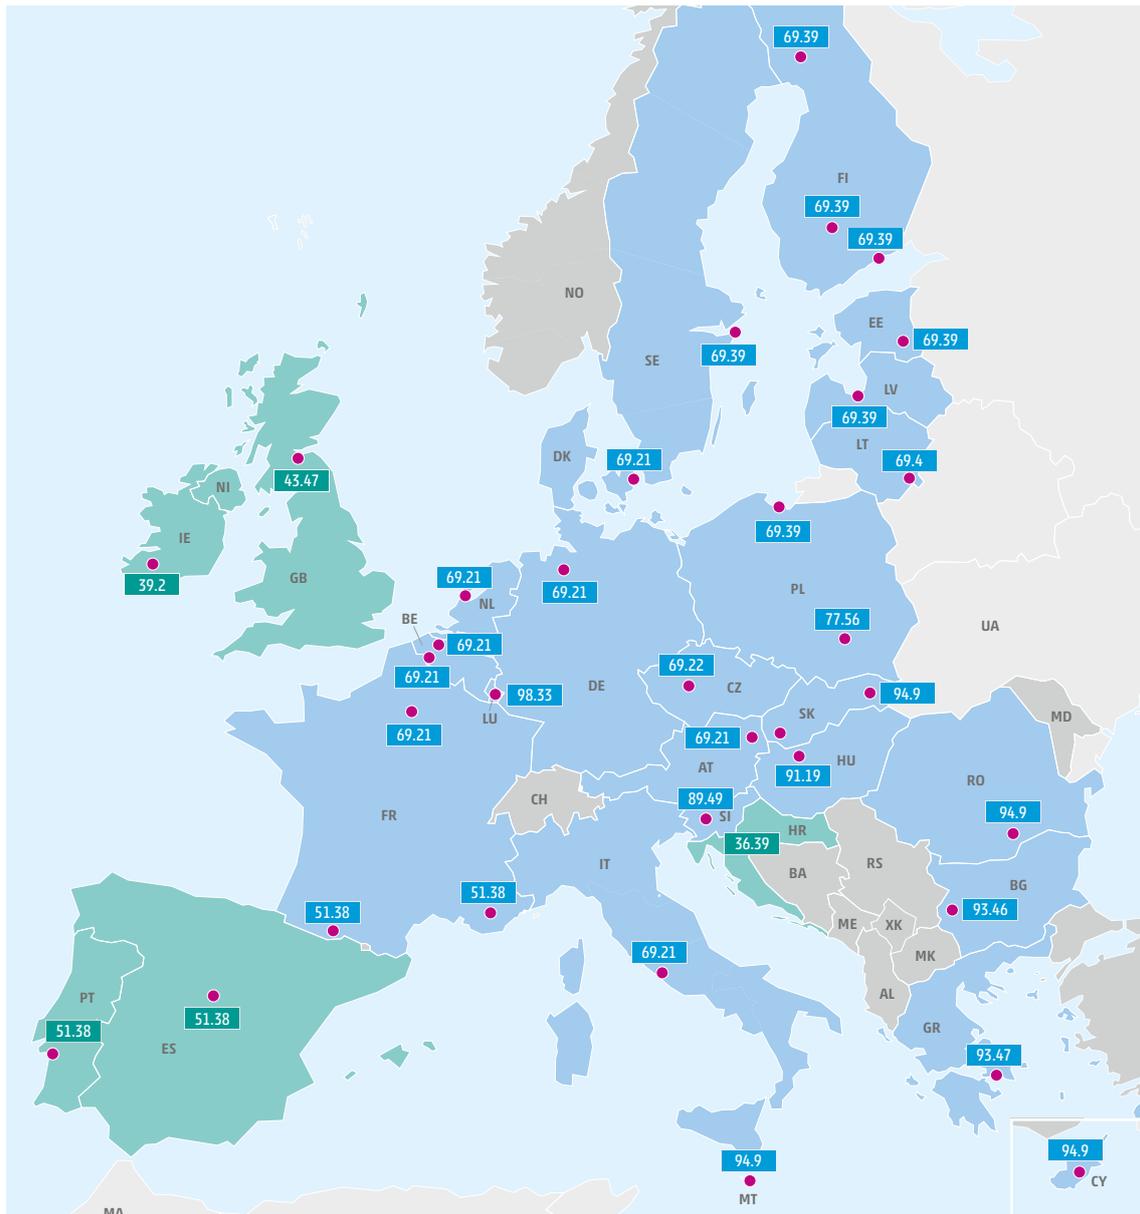

Figure 9: Average of the hourly hydrogen market clearing prices per country in the PCI/PMI hydrogen infrastructure level in 2030 (unit: €/MWh).

The price formation in the DHEM is based on the merit order of hydrogen production (see section 4.1). Several price groups stand out, while a significant correlation is understood here as a correlation above 0.7:

- 1. Portugal, Spain, France-South region:** Portugal and Spain are producers and net exporters of electrolytic hydrogen from RES to other countries. While the France-South region is sufficiently connected to the Iberian Peninsula, price spreads appear with other groups of countries due to an internal bottleneck in France. The prices in this group show a significant correlation with the prices in groups 2, 3 and 4.
- 2. France-Southwest region:** Local undersupply and isolated from other French regions. The prices in this group show significant correlations with prices in groups 1, 3 and 4.
- 3. Belgium, the Netherlands, Denmark, Germany, Czechia, Austria, Italy:** Well interconnected countries that as group have own import terminals and national hydrogen production and are in the centre of two main supply corridors. The prices in this group show a nearly perfect correlation with the prices in group 4 and a significant correlation with the prices in groups 1 and 2.
- 4. Sweden, Finland, Estonia, Latvia and Lithuania:** Composed of net exporting countries Sweden and Finland as well as countries that are well interconnected without bottlenecks. The prices are very similar to the prices in group 3 as the bottlenecks between the two groups play a minor role. The prices in this group show a nearly perfect correlation with the prices in group 3 and a significant correlation with the prices in groups 1 and 2.
- 5. Ireland, the United Kingdom, Croatia, Poland-South region:** Isolated (regions of) countries without significant price correlations but with average prices below 100 €/MWh.
- 6. Greece, Bulgaria:** Countries showing significant price correlation, jointly isolated from the other European countries.
- 7. Slovenia, Hungary, Romania, Luxembourg, Cyprus, Slovakia, Malta:** Isolated countries without significant price correlations (except for Hungary and Slovenia due to a similar national hydrogen production constellation) and with average prices above 100 €/MWh.

The price correlations listed above are enabled by the infrastructure projects already considered in this hydrogen infrastructure level. However, price differences that led to the identification of the groups listed above are not necessarily describing an infrastructure gap. For this identification of infrastructure gaps, the thresholds of IGI indicator 1 are used.

Picture courtesy of GASSCO

Hydrogen market clearing price spreads

If one of the two thresholds of IGI indicator 1 is passed, a regional hydrogen infrastructure gap is assumed to be identified (see section 4.1). Table 11 lists the borders for which Threshold 1

and/or Threshold 2 were passed. In this case, both thresholds were always passed at the same borders.

Border	Threshold 1: Absolute average hourly hydrogen market clearing price spread above 4 €/MWh (number of days)	Threshold 2: More than 40 days with hydrogen market clearing price spread above 20 €/MWh (number of days)
DEh ₂ -PLh ₂ S	26	169
FRh ₂ -FRh ₂ S	26	168
FRh ₂ -FRh ₂ SW	12	66
FRh ₂ S-FRh ₂ SW	19	99
HUh ₂ -ATH ₂	32	233
HUh ₂ -HRh ₂	80	365
HUh ₂ -ROh ₂	5	43
HUh ₂ -SKh ₂ E	5	43
ITh ₂ -HRh ₂	50	293
NLh ₂ -UKh ₂	42	228
PLh ₂ N-PLh ₂ S	25	167

UKh ₂ -IEh ₂	19	111

Table 11: List of borders in the PCI/PMI hydrogen infrastructure level that exceed (at least one of) the thresholds defined for IGI indicator 1 in 2030 (unit: days).

6.1.1.2 IGI INDICATOR 2.1: HYDROGEN DEMAND CURTAILMENT FOR REFERENCE WEATHER YEAR

As explained in section 4.2, this IGI indicator assesses infrastructure gaps by quantifying hydrogen demand curtailments at individual nodes during the reference weather year, assuming no disruptions of infrastructures or of supply sources. It involves a multi-step simulation process integrating DHEM and DGM¹⁰ outputs to evaluate the combined curtailments across nodes. The assessment is performed for the PCI/PMI hydrogen infrastructure level in 2030.

Figure 10 and Table 12 show yearly average curtailment rates of hydrogen demand in the Zone 2 nodes of different European countries. For countries where the hydrogen market is divided into several sub-zones (i.e., nodes), the curtailment rate in the different sub-zones is presented. The yearly average hydrogen curtailment rates are thereby colour-coded in the map to indicate levels relative to the set threshold: blue signifies curtailment above the threshold, while green represents rates that are not above it.

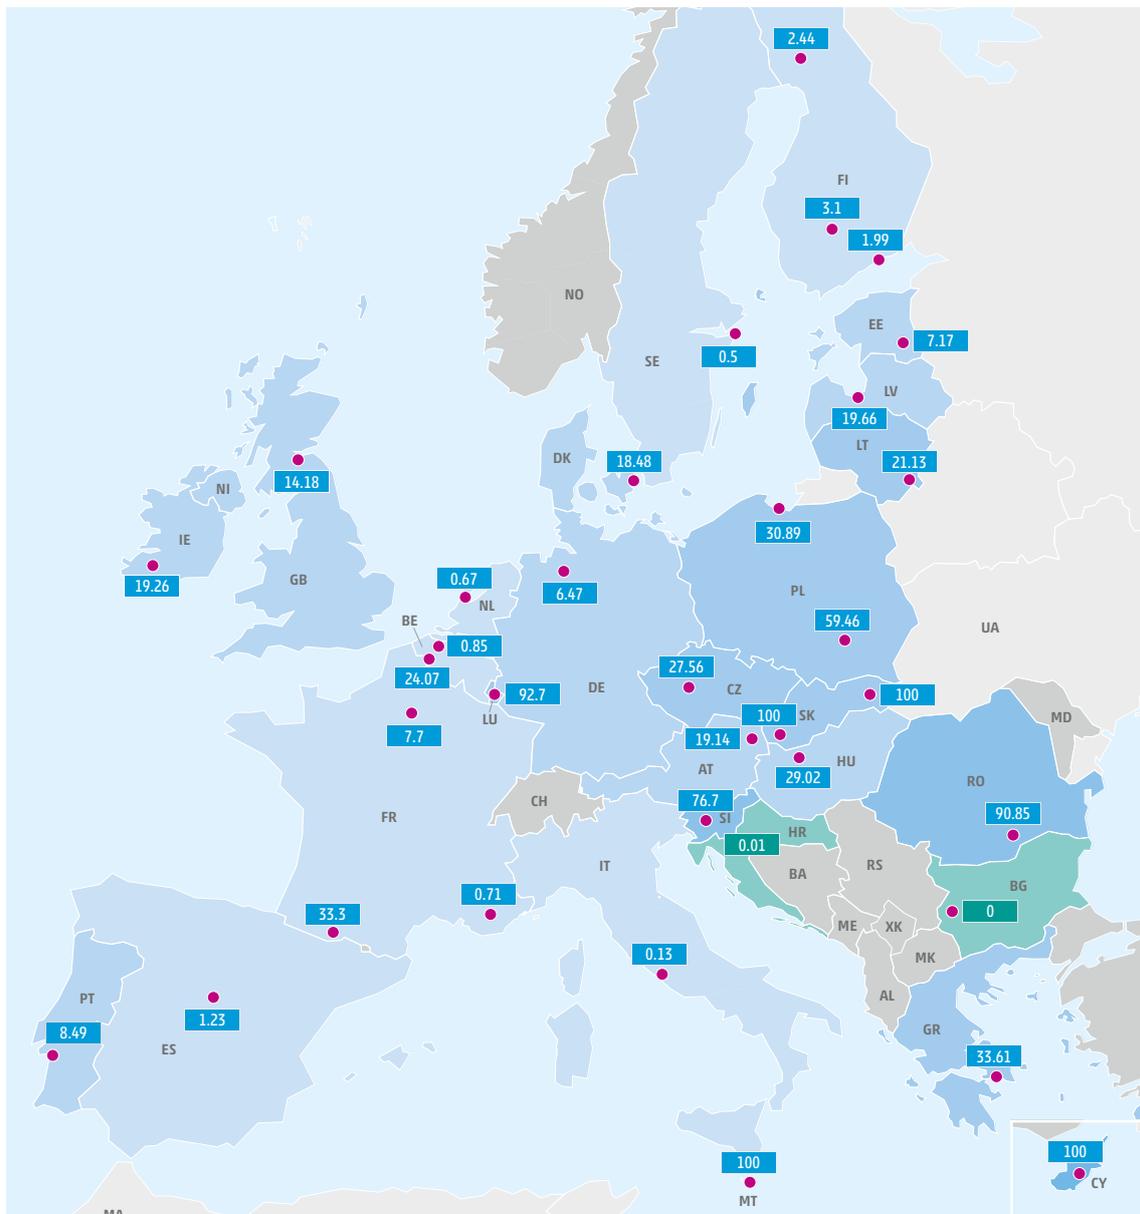

Figure 10: Yearly average hydrogen demand curtailment rate at country/sub-zone level in the PCI/PMI hydrogen infrastructure level in 2030 for reference weather year (unit: %).

¹⁰ This draft TYNDP 2024 IGI report only includes the simulation results of the DHEM.

Table 12: Yearly average hydrogen demand curtailment rate at country/sub-zone level in the PCI/PMI hydrogen infrastructure level in 2030 for reference weather year and check of the threshold of IGI indicator 2.1 (unit: %).

In the 2030 assessment of the PCI/PMI hydrogen infrastructure level, hydrogen demand is curtailed all over Europe. However, differences in the hydrogen curtailment rates between nodes are related to the level of infrastructure development and supply availability.

As explained in the description of the PCI/PMI hydrogen infrastructure level (see section 3 and Figure 1), with limited availability of extra-EU supplies, hydrogen demand is satisfied mainly with electrolytic hydrogen production and hydrogen production from natural gas.

Countries with higher availability of supply from those sources or from imports show lower curtailment rates. Only Bulgaria and Croatia hydrogen demand is completely undisrupted and the hydrogen demand curtailment in Italy is very low. All other countries including strong net exporters face (weather-induced) disruptions. In comparison with IGI indicator 1, this IGI indicator focusses on the availability of supplies.

As detailed in Figure 11, (regions of) countries can be aggregated in six different groups according to their average yearly hydrogen demand curtailment rates:

- 1. Rates below 0.1 %:** Bulgaria, Croatia.
- 2. Rates between 0.1 % and 5 %:** Italy, Belgium, Finland, France-South region, the Netherlands, Spain, Sweden.
- 3. Rates between 5 % and 20 %:** France, Austria, Denmark, Estonia, Germany, Ireland, Latvia, Portugal, the United Kingdom.
- 4. Rates between 20 % and 50 %:** Belgium-Mons region, Czechia, France-Southwest region, Hungary, Lithuania, Poland-North region, Greece.
- 5. Rates between 50 % and 100 %:** Slovenia, Romania, Poland-South region, Luxembourg.
- 6. Full curtailment of 100 %:** Slovakia, Cyprus, Malta.

Without the infrastructure already considered in the hydrogen infrastructure level, the overall hydrogen demand curtailment would be higher.

All countries of group 1 have high shares of hydrogen produced from natural gas to cover national demand.

Among the countries of group 2, Spain, Sweden and Finland receive a significant share of their supply from national electrolytic hydrogen production, while Belgium, and the Netherlands, have access to extra-EU import capacities. The France-South region benefits from potential supplies from the Iberian Peninsula but also from other parts of France. At the same time, while the average demand curtailment is comparably low, all relevant nodes at certain hours of the year hit very high curtailment rates between 84 % in Spain, 89 % in Germany, and 100 % in the other nodes.

Among the countries of group 3, some countries like Denmark, Portugal, the United Kingdom and Ireland, despite having significant electrolytic hydrogen production compared to the national demand, still cannot cover all demand when RES are not available. In the case of Denmark and Portugal, being peripheral countries, their neighbouring countries (i.e., Germany and Spain) can help to mitigate demand curtailment, whereas in the case of the United Kingdom and Ireland, being isolated from Europe leads to higher curtailment rates. Among the countries of group 3, some countries such as Austria, Estonia, Germany and Latvia, despite being well interconnected, show demand curtailment mainly due to the limited availability of supplies for the EU in general that are then rather consumed closer to the location of production or import. For France, different curtailment rates are observed between the different hydrogen nodes. The France-Southwest region is the area with higher curtailment (i.e., 33.3 %) as it is isolated and strictly depends on local production. Between the other two demand nodes in France (i.e., France and France-South regions) there is 7 % of difference in the demand curtailment due to privileged access of the France-South region to supply from the Iberian Peninsula.

Among the countries of group 4, some countries like Czechia and Lithuania show high curtailment rates (i.e., 27.6 % and 21.1 %), despite being connected to Germany, in case of Czechia and other Baltic Sea countries, in case of Lithuania. This is because both countries need significant imports from their neighbouring countries to satisfy demand while the neighbouring countries at certain periods of time do not have access to surplus supplies for export. In addition, national production in Lithuania represents a higher share of the demand in comparison with the Czech Republic. Greece shows a curtailment rate of 33.3 %, which can be explained by the fact that despite being interconnected with Bulgaria, both countries are isolated from the rest of Europe (see section 3 and Figure 1). Lastly, the Belgium-Mons region is designed to be an individual cluster only connected to France (Valenciennes production cluster) and not interconnected to the remaining Belgian grid in the PCI/PMI hydrogen infrastructure level in 2030. Due to this isolated situation, curtailment is significantly higher (i.e., 24.1 %) than in the rest of the country (i.e., 0.9 %).

Group 5 includes countries with very high curtailment rates of up to nearly 100 %. All the countries in this group are fully isolated and rely on national hydrogen supplies, mainly produced from natural gas. This is also the case for the Poland-South region that shows a curtailment rate of almost 60 %, whereas the Poland-North region has a curtailment rate of around 31 % due to higher hydrogen generation in that region.

Group 6 includes only isolated countries that have hydrogen demand but no national hydrogen production assets connected to Zone 2.

In Denmark, Finland, Ireland, Sweden, and Slovenia, on top of the hydrogen demand curtailments observed in Zone 2 nodes as described in the paragraphs above, hydrogen demand curtailments can be observed in Zone 1. While these curtailments are limited to a few months in Sweden and Finland, it is of relevance in every month in Ireland and reaches up to 86 % in December in Denmark and up to 96 % in December in Slovenia.

6.1.1.3 IGI INDICATOR 2.2: HYDROGEN DEMAND CURTAILMENT FOR STRESSFUL WEATHER YEAR

Threshold 1: Average yearly hydrogen demand curtailment rate above 3 %

Figure 11 and Table 13 show the yearly average hydrogen demand curtailment rates in the Zone 2 nodes of various European countries for 2030, simulated under a stressful weather year. This weather scenario assumes adverse conditions, such as reduced wind and solar energy availability, which directly impacts hydrogen production. For countries with hydrogen markets divided into mul-

iple sub-zones (i.e., nodes), curtailment rates are depicted individually for each sub-zone on the map. The yearly average hydrogen curtailment rates are thereby colour-coded to indicate levels relative to the set threshold 1: blue signifies curtailment above the threshold, while green represents rates that are not.

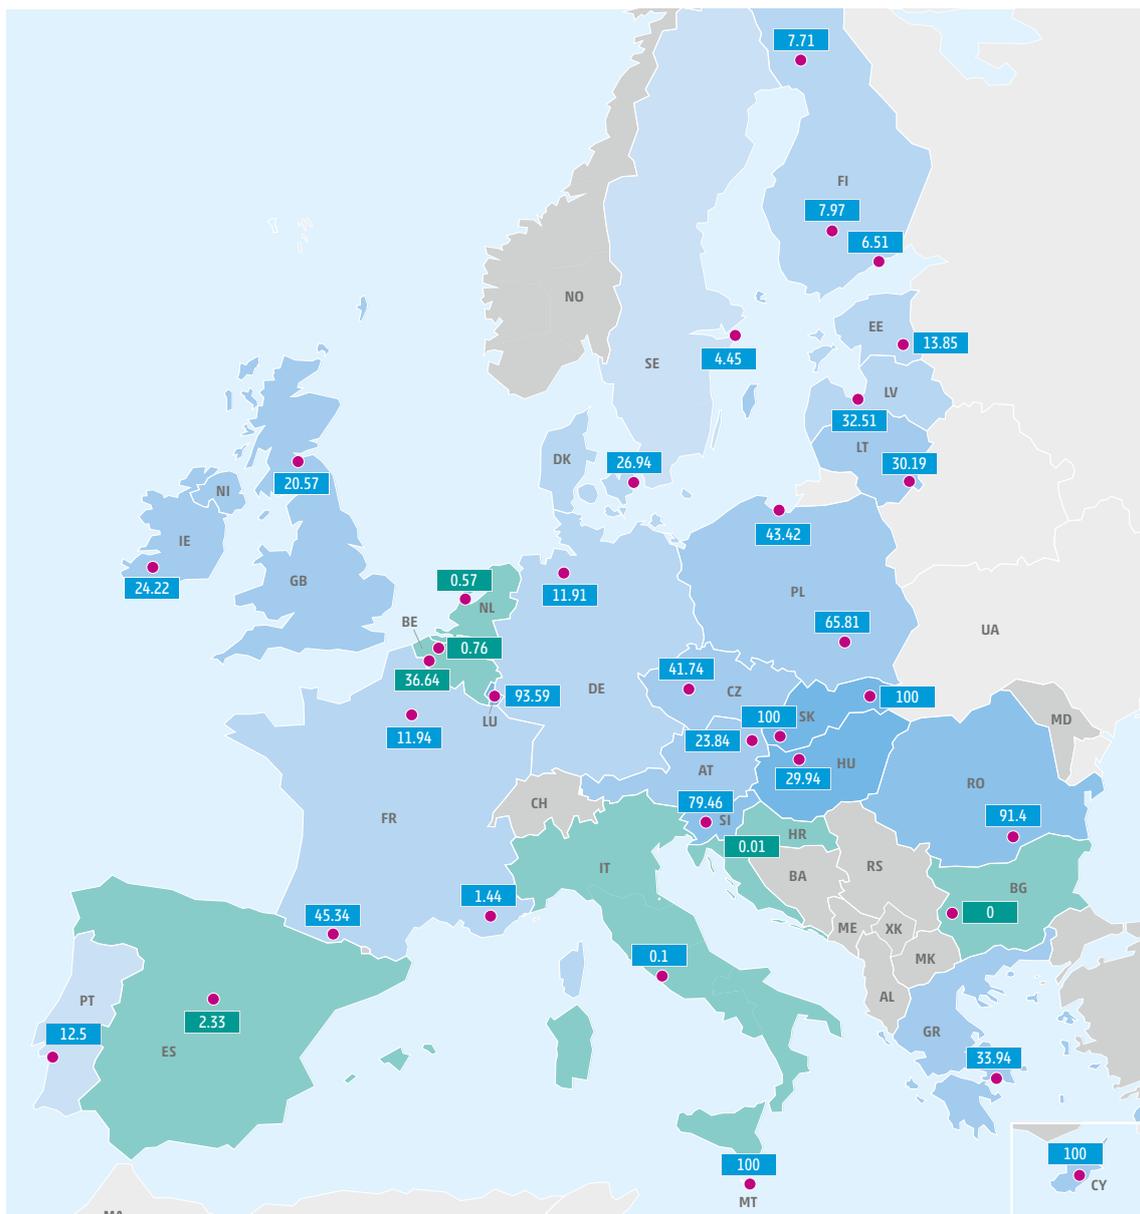

Figure 11: Yearly average hydrogen demand curtailment rate at country or node level in the PCI/PMI hydrogen infrastructure level in 2030 for stressful weather year (unit: %).

Table 13: Yearly average hydrogen demand curtailment rate at country/sub-zone level in the PCI/PMI hydrogen infrastructure level in 2030 for stressful weather year and check of threshold 1 of IGI indicator 2.2 (unit: %).

As detailed in Figure 11, countries can be aggregated in different groups according to their average yearly hydrogen demand curtailment rates:

- 1. Rates below 3 %:** France-South region, Spain, the Netherlands, Croatia, Italy, Belgium, Bulgaria.
- 2. Rates between 3 % and 20 %:** Sweden, Portugal, France, France-North region, Finland, Estonia, Germany.
- 3. Rates above 20 % and below 50 %:** Belgium-Mons, Latvia, Lithuania, Ireland, Hungary, Greece, Denmark, Czechia, Austria, Poland North.
- 4. Rates above 50 % and below 100 %:** Slovenia, Romania, Poland South, Luxembourg.
- 5. Full curtailment of 100 %:** Slovakia, Cyprus, Malta.

Based on Table 13, the countries that have a yearly average hydrogen demand curtailment rate below 3 % in the stressful weather year are Spain, France-South region, the Netherlands, Croatia, Italy, Belgium, and Bulgaria.

The second group of countries includes Sweden, Portugal, France, the France-North region, Finland, Estonia, and Germany. These nations exhibit demand curtailment rates exceeding the defined threshold 1 but remaining at or below 20 %. This trend can be attributed to the composition of the composition of their hydrogen production means. For instance, Sweden, with a demand curtailment rate of 4.95 %, leverages a substantial share of wind and hydropower, ensuring greater stability in its hydrogen supply. Finland is comparable to Sweden, while France demonstrates a 12 % demand curtailment rate, where its reliance on nuclear energy mitigates dependence on fluctuating climatic conditions, enhancing supply availability. Germany benefits from its proximity to multiple supply options as it is in the centre of the Iberian and the Nordic corridor, has own import terminals, and has access to terminals in neighbouring countries.

The third group encompasses Belgium-Mons, Latvia, Lithuania, Ireland, Hungary, Greece, Denmark, Czechia, and Austria. This cohort includes

countries like Greece (33.94 %) and Denmark (26.94 %) alongside others such as Czechia and Ireland, which face challenges stemming from their relative isolation within the hydrogen production and distribution topology. Geographic and infrastructural isolation increases reliance on domestically produced hydrogen, particularly from RES. Furthermore, dependency on imports from a single connected country—similarly affected by climatic stress—limits the availability of external hydrogen supplies. In such cases, countries prioritize domestic needs over exports, further constraining the import options for these isolated or peripheral regions.

The fourth group contains Slovenia, Romania, Poland and Luxembourg that show annual average hydrogen demand curtailment rates that exceed 50 % but remain below 100 % under the stressful weather year. The high curtailment rate observed in Luxembourg can be primarily attributed to the absence of interconnections with the neighbouring countries in the PCI/PMI hydrogen infrastructure level in combination with low national hydrogen production options. In Poland, which is divided into a northern region and a southern region, the southern region experiences notably higher curtailment rates under the stressful weather year due to lower hydrogen generation in the Poland-South region than in the Poland-North region. This disparity arises also due to a lack of sufficient PCI infrastructure which, combined with intensified weather impacts, significantly limits the ability to meet hydrogen demand. Romania and Slovenia also encounter substantial curtailments. In both countries, limited infrastructure in the PCI/PMI hydrogen infrastructure level in 2030 results in considerable hydrogen demand curtailment, regardless of weather variability. Consequently, while weather conditions play a role, they are not the primary factor in the persistently high curtailment rates observed in these countries.

Full demand curtailment under the stressful weather year has been identified for Slovakia, Malta and Cyprus, as has been the case for the reference weather year. These countries are fully isolated in the PCI/PMI hydrogen infrastructure level in 2030 and have no national hydrogen production assets connected to Zone 2.

Threshold 2: hydrogen demand curtailment rate of more than 5 % for at least one month per year

All the countries and regions that exceed threshold 1 also exceeded threshold 2.

6.1.2 ASSESSMENT OF ADVANCED HYDROGEN INFRASTRUCTURE LEVEL

High-level results for reference weather year

In 2030, compared to the PCI/PMI hydrogen infrastructure level, the advanced infrastructure level considers several new infrastructures (see section 3.2): Besides a connection between Algeria and Italy, Slovakia, Hungary and Romania are connected to Germany, Poland and Czechia instead of being isolated.

The overall yearly supply-demand balance for the advanced infrastructure level in 2030 for the reference weather year is presented in Table 14. As detailed in Table 14, electrolytic hydrogen

production is the main source of hydrogen in Europe. This assessment results in an approximate share of 4.3 % of hydrogen demand curtailment in Europe. This is a significant decrease compared to the curtailment rate of 8.3 % for the PCI/PMI hydrogen infrastructure level. Thereby, electrolytic hydrogen production, hydrogen production from natural gas and imports via terminals are all slightly reduced on yearly average as Algerian supply is partially replacing these supplies due to the merit order besides decreasing the hydrogen demand curtailment.

Yearly hydrogen supply-demand balance	Advanced IL
H₂ produced via electrolysis	304
H₂ produced using natural gas	224
H₂ shipped imports	24
H₂ pipeline imports	42
Curtailed H₂ demand	27
H₂ demand for power production	2
Total H₂ demand	620

Table 14: Supply and demand balance in the Advanced hydrogen infrastructure level in 2030 for reference weather year (unit: TWh/y).

Figure 12 shows the hydrogen production via electrolysis in the different European countries for the Advanced hydrogen infrastructure level in the 2030 assessment. The countries with highest electrolytic hydrogen production are Spain, Finland, Sweden,

and Germany. Some countries have more than one source of electrolytic hydrogen production. This is related to the intra-country assumptions, which is explained in section 6.1.1.

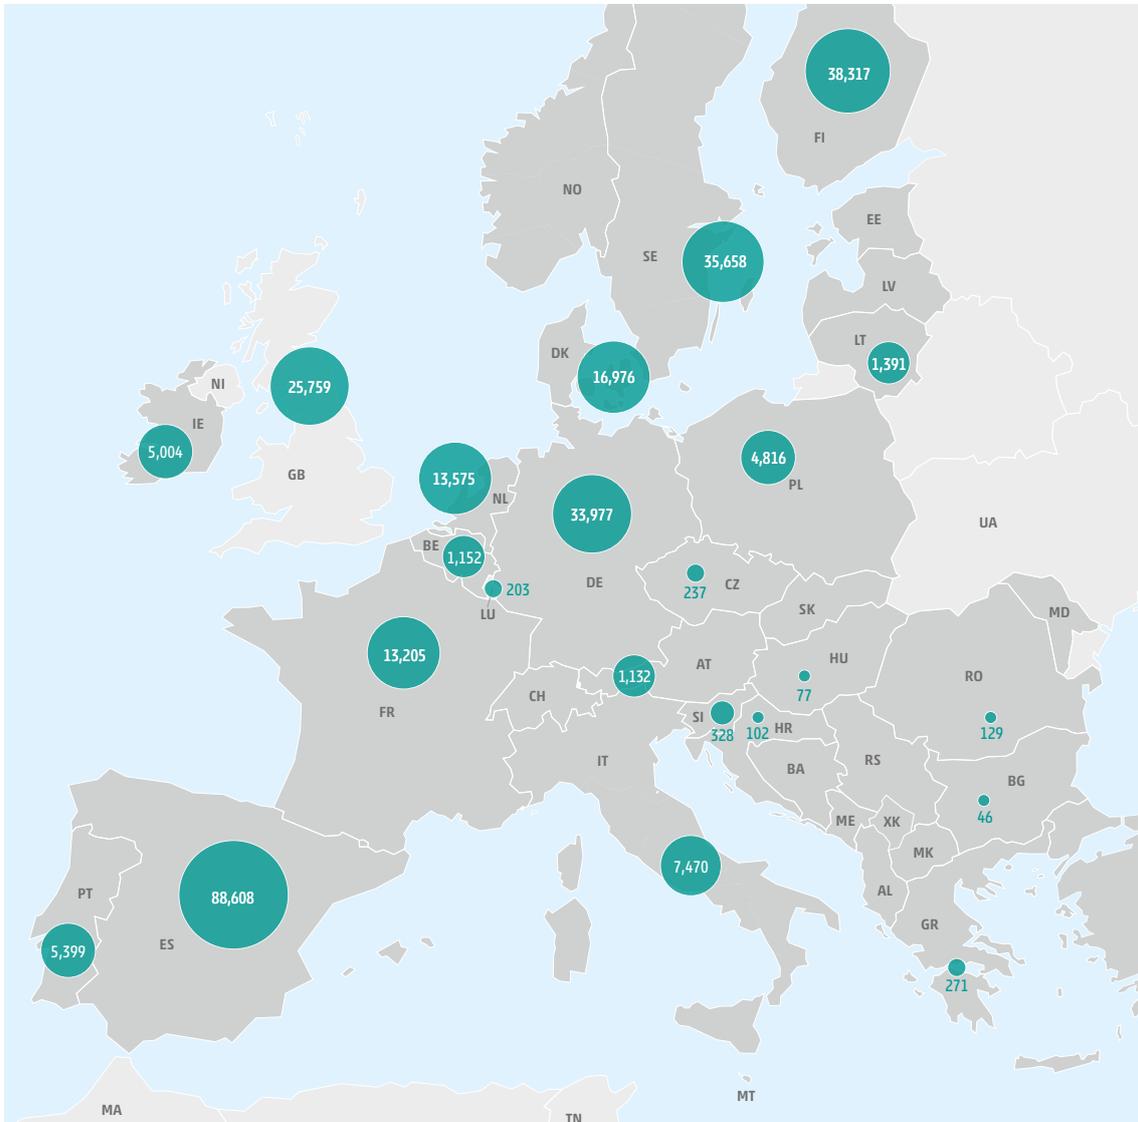

Figure 12: Distribution of hydrogen production via electrolysis in the Advanced hydrogen infrastructure level in 2030 for reference weather year (unit: GWh/y).

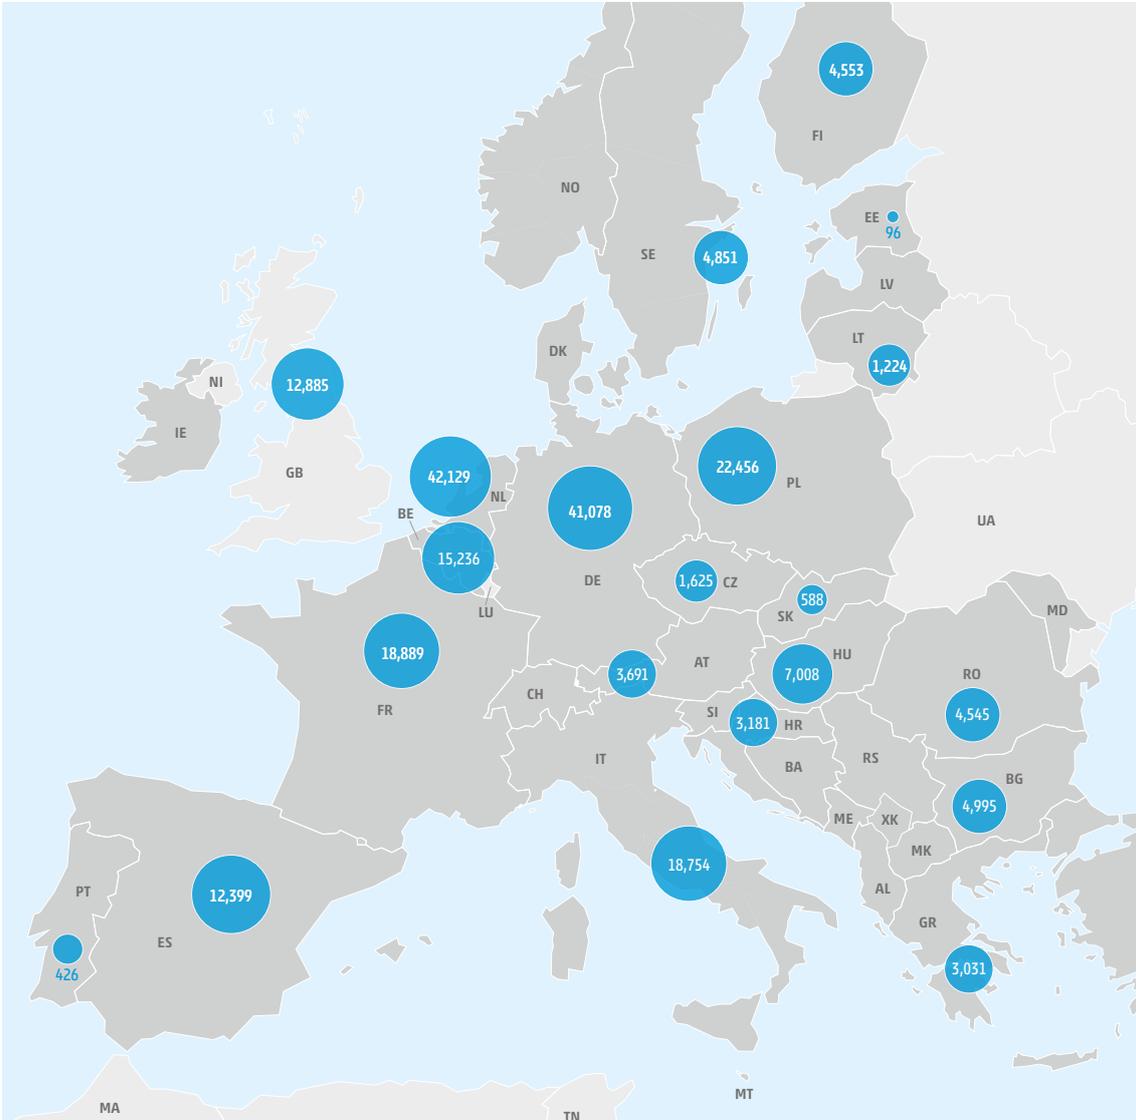

Figure 13: Distribution of hydrogen production from natural gas in the advanced infrastructure level in 2030 for reference weather year (unit: GWh/y).

Table 15: Distribution of hydrogen production, demand and hydrogen imports per country in the Advanced hydrogen infrastructure level in 2030 for reference weather year (unit: GWh/y).

Intra-EU cross-border flows emerge between different European countries due to limitations of available supplies and associated costs. Figure 14 shows these flows.

Compared to the PCI/PMI hydrogen infrastructure level, which contains the Iberian and the Nordic corridor, a new main corridor emerged in the advanced infrastructure level:

- ▲ North African corridor, transporting e.g. Algerian supplies to Italy, Austria, Germany and other countries.

In addition, among the interconnected countries within the advanced infrastructure level, new interconnections with Slovakia, Hungary and Romania enable new flows to these countries from German/Czechian and Austrian hubs.

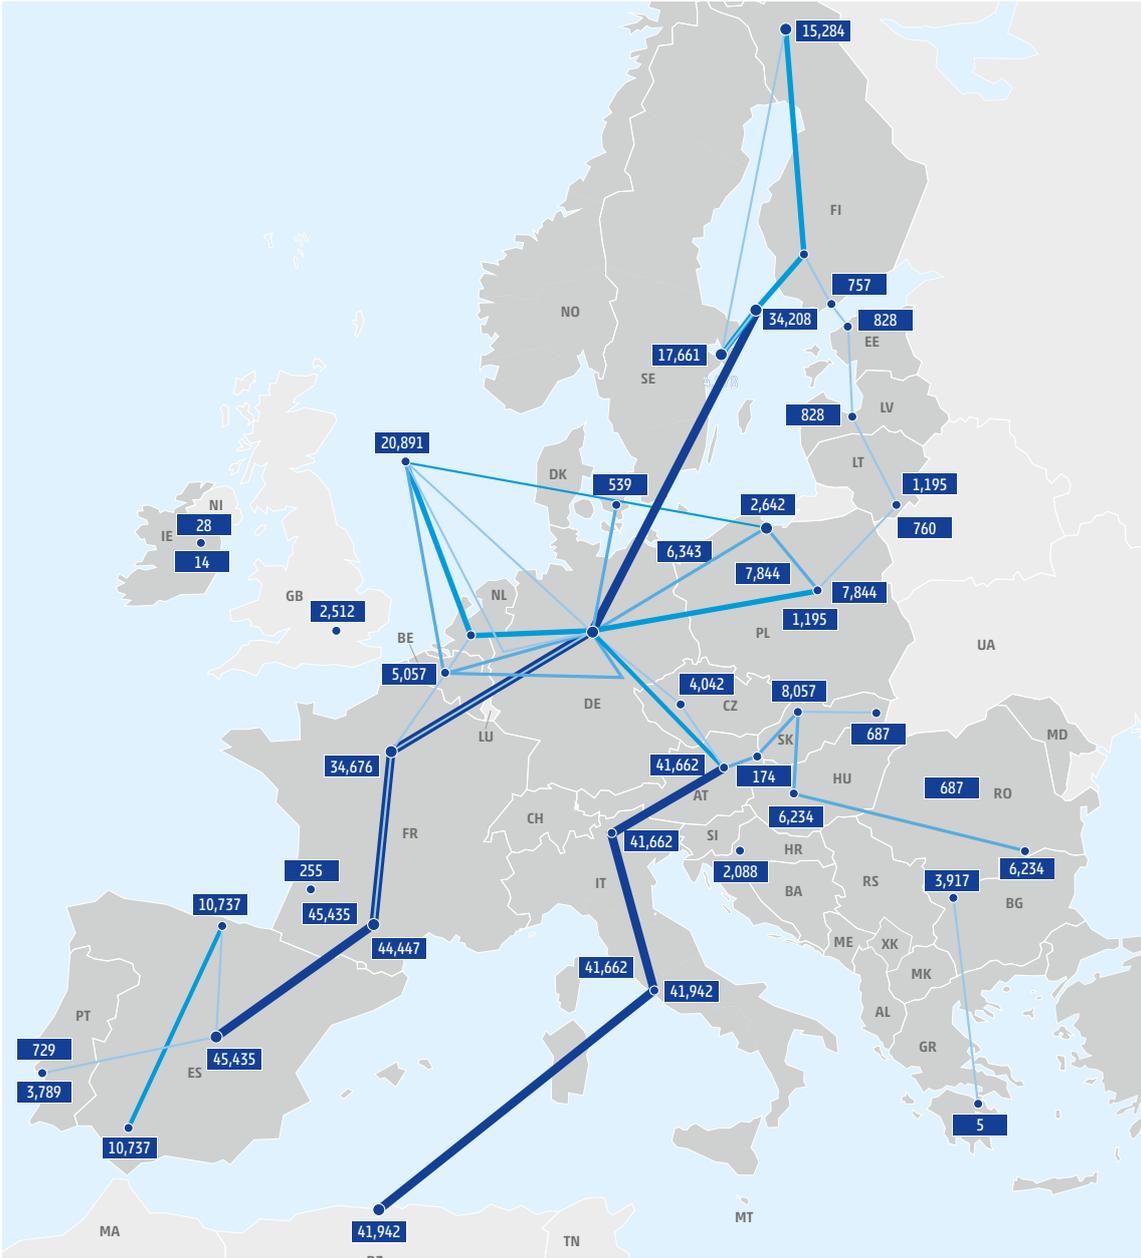

Figure 14: Grid flows* in the advanced infrastructure level in 2030 for reference weather year (unit: GWh/y).

* Grid flows refer to simulations results and don't intend to represent how the European infrastructure is expected to evolve in the simulated years, being just outcomes of a modelling tool. The values are provided as a table in Annex II and as monthly values in Annex III).

In the 2030 Advanced infrastructure level assessment countries can be grouped in four different categories according to their supply-demand balance on a yearly basis:

- 1. Countries that export more than they import:** Sweden, Finland, Denmark, Spain, Portugal and Bulgaria.
- 2. Countries that import more than they export:** Poland, Czechia, Greece, Romania and Belgium.
- 3. Transit countries that import more than they consume:** Germany, Italy, Austria, France, Netherlands, Estonia, Latvia, Lithuania, Slovakia, Hungary.
- 4. Isolated countries:** The United-Kingdom, Ireland, Luxembourg, Slovenia, Croatia, Malta, Cyprus, Switzerland¹¹ and the cluster Bulgaria-Greece.

In comparison with the PCI/PMI hydrogen infrastructure level, Italy will change from exporting role to transit country due to the availability of North African supplies. In addition, Slovakia, Romania and Hungary could overcome isolation, and Austria changed from group 2 to group 3.

While on a yearly basis some countries are net exporters and some countries are net importers, net exporters may be relying on net imports during certain shorter periods of time and net importers may be providing net exports during certain shorter periods of time. This can result in bidirectional flows at interconnections. This situation is caused by the seasonality of electrolytic hydrogen production and to some extent by the seasonality of hydrogen demand.

High-level results for stressful weather year

The overall yearly supply-demand balance for the Advanced hydrogen infrastructure level in 2030 for the stressful weather year is presented in Table 16. As detailed in Table 16, electrolytic hydrogen production is the main source of hydrogen in Europe but it is reduced in comparison with the reference

weather year and is partially compensated by increase used of SMR. This assessment results in an approximate share of 6.1 % of curtailed hydrogen demand at European level. This represents an increase by 2 percentage points in comparison with the reference weather year.

Yearly hydrogen supply-demand balance	Advanced IL
H₂ produced via electrolysis	265
H₂ produced using natural gas	241
H₂ shipped imports	35
H₂ pipeline imports	42
Curtailed H₂ demand	38
H₂ demand for power production	2
Total H₂ demand	620

Table 16: Supply and demand balance in the advanced infrastructure level in 2030 for stressful weather year (unit: TWh/y).

¹¹ IGI report does not consider hydrogen demand in Switzerland (based on TYNDP 2024 Draft Scenario report). However, there is no hydrogen infrastructure connecting Switzerland to any of its European neighbouring countries in the assessed infrastructure levels.

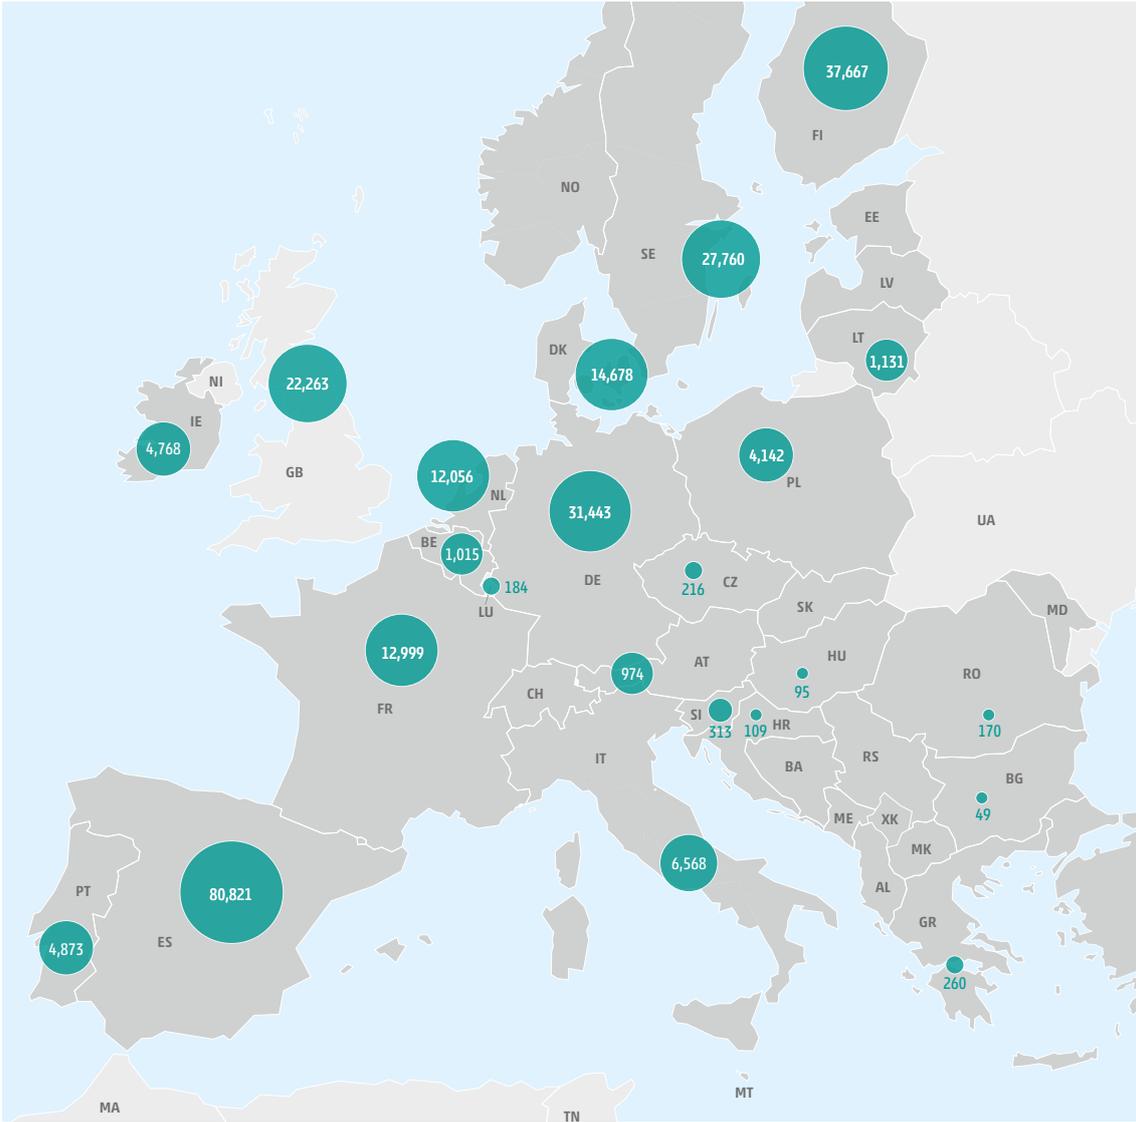

Figure 15: Distribution of hydrogen production via electrolysis in the advanced infrastructure level in 2030 for stressful weather year (unit: GWh/y).

4. Italy: Due to its access to Algerian imports and a capacity between Italy and Austria that sometimes acts as a bottleneck, meaning that capacity at this interconnection point is utilized at its maximum potential not allowing further exports (therefore, signalling needs for potential enhancements), Italy is an own price region. It has significant correlation with prices in group 1 and group 3.

5. Ireland, the United Kingdom, Poland-South region: Isolated (regions of) countries without significant price correlations but with average prices below 100 €/MWh.

6. Greece, Bulgaria: Countries showing significant price correlation, jointly isolated from the other European countries.

7. Slovenia, Luxembourg, Croatia, Cyprus, Malta: Isolated countries without significant price correlations and with average prices above 100 €/MWh. The price correlations listed above are enabled by the infrastructure projects already considered in this hydrogen infrastructure level. However, price differences that led to the identification of the groups listed above are not necessarily describing an infrastructure gap. For this identification of infrastructure gaps, the thresholds of IGI indicator 1 are used.

Border	Threshold 1: Absolute average hourly hydrogen market clearing price spread above 4 €/MWh (number of days)	Threshold 2: More than 40 days with hydrogen market clearing price spread above 20 €/MWh (number of days)
DE _{H₂} –PL _{H₂S}	29	182

Table 18: List of borders in the advanced infrastructure level that exceed (at least one of) the thresholds defined for IGI indicator 1 in 2030 (unit: days).

Hydrogen market clearing price spreads

If one of the two thresholds of IGI indicator 1 is passed, a regional hydrogen infrastructure gap is assumed to be identified (see section 4.1). Table 18 lists the borders for which Threshold 1 and Threshold 2 were passed. In this case, both thresholds were always passed at the same borders.

In comparison with the PCI/PMI hydrogen infrastructure level, the price spreads at the following borders decreased below the thresholds through the additional infrastructure of the Advanced hydrogen infrastructure level (see Figure 19):

- ▲ Hungary: Borders with Austria, Romania, Slovakia.
- ▲ Slovakia: Borders with Austria and Czechia.

6.1.2.2 IGI INDICATOR 2.1: HYDROGEN DEMAND CURTAILMENT FOR REFERENCE WEATHER YEAR

As explained in section 4.2, this IGI indicator assesses infrastructure gaps by quantifying hydrogen demand curtailments at individual nodes during the reference weather year, assuming no disruptions of infrastructures or of supply sources. It involves a multi-step simulation process integrating DHEM and DGM¹² outputs to evaluate the combined curtailments across nodes. The assessment is performed for the Advanced hydrogen infrastructure level in 2030.

Figure 19 and Table 19 show yearly average curtailment rates of hydrogen demand in the Zone 2 nodes of different European countries. For countries where the hydrogen market is divided into several sub-zones (i.e., nodes), the curtailment rate in the different sub-zones is presented. The yearly average hydrogen curtailment rates are thereby colour-coded in the map to indicate levels relative to the set threshold: blue signifies curtailment above the threshold, while green represents rates that are not above it.

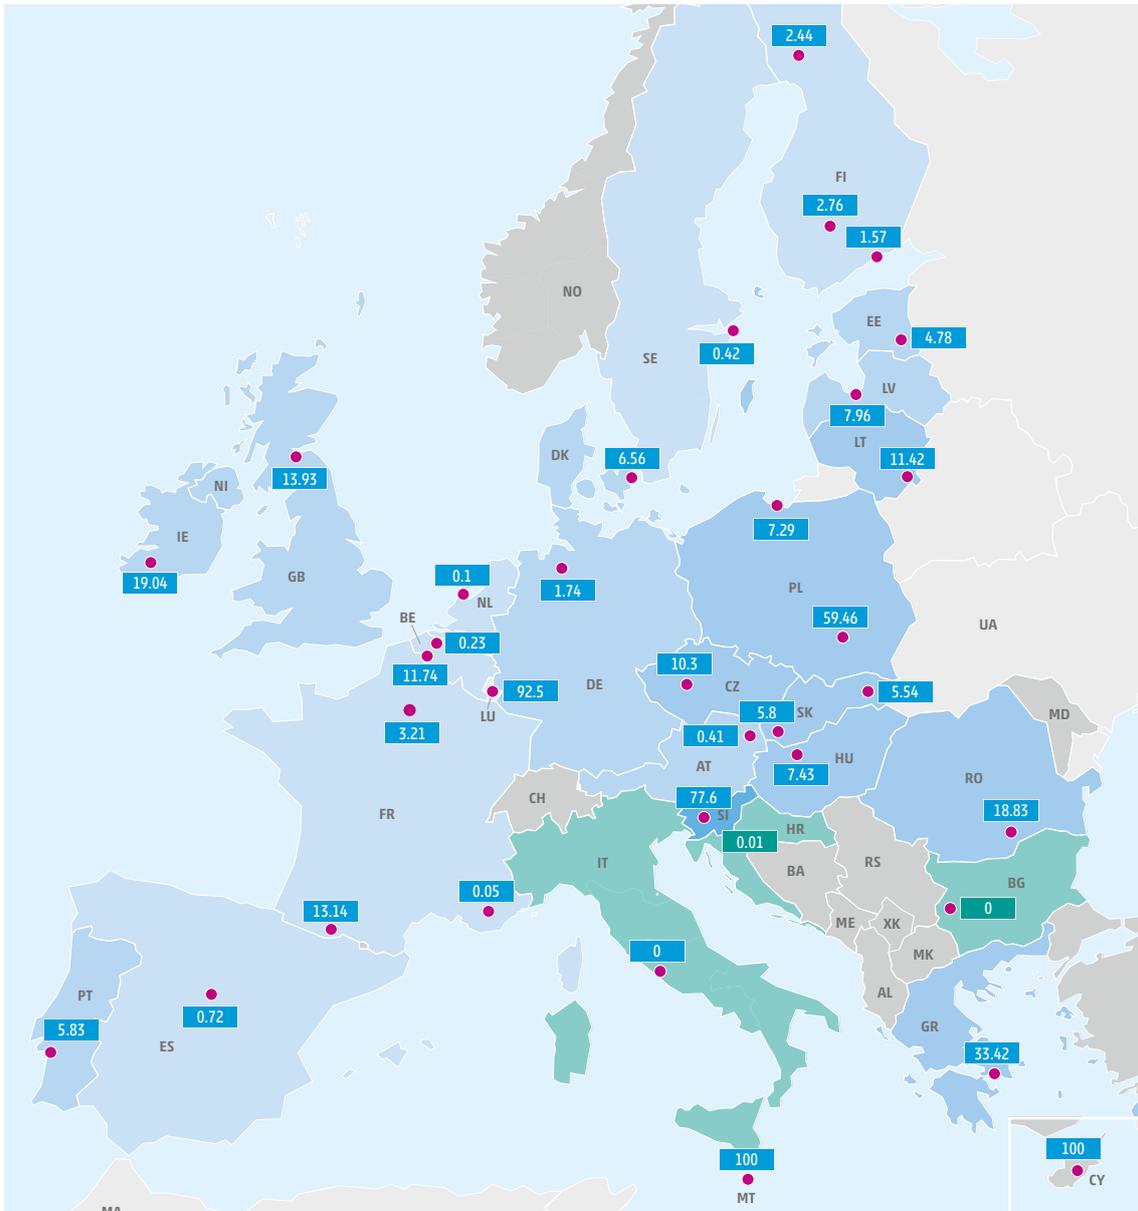

Figure 19: Yearly average hydrogen demand curtailment rate at country or node level in the advanced infrastructure level in 2030 for reference year (unit: %).

12 This draft TYNDP 2024 IGI report only includes the simulation results of the DHEM.

Table 19: Yearly average hydrogen demand curtailment rate at country/sub-zone level in the advanced infrastructure level in 2030 for reference weather year (unit: %).

In the 2030 assessment of the advanced infrastructure level, hydrogen demand is curtailed in most European countries.

As explained in the description of the Advanced hydrogen infrastructure level (see section 3.2), with limited availability of extra-EU supplies, hydrogen demand is satisfied mainly with electrolytic hydrogen production and hydrogen production from natural gas. Countries with higher availability of supply from those sources or from imports show lower curtailment rates. Most countries including strong net exporters face (weather-induced) disruptions. In comparison with IGI indicator 1, this IGI indicator focusses on the availability of supplies.

As detailed in Table 19, (regions of) countries can be aggregated in six different groups according to their average yearly hydrogen demand curtailment rates:

- Rates below 0.1 %:** Bulgaria, Croatia, Italy, France-South region, the Netherlands.
- Rates between 0.1 % and 5 %:** Belgium, Austria, Finland, Germany, Spain, Sweden, France, Estonia.
- Rates between 5 % and 20 %:** Denmark, Poland-North region, Hungary, Ireland, Latvia, Lithuania, Portugal, Belgium-Mons region, Czechia, Slovakia, France-Southwest region, Romania, the United Kingdom.
- Rates between 20 % and 50 %:** Greece.
- Rates between 50 % and 100 %:** Slovenia, Poland-South region, Luxembourg.
- Full curtailment of 100 %:** Cyprus, Malta.

Without the infrastructure already considered in the hydrogen infrastructure level, the overall hydrogen demand curtailment would be higher.

Compared with the PCI/PMI hydrogen infrastructure level, group 1 also includes the France-South region and the Netherlands. All countries in this group do not face any hydrogen demand disruption (i.e., 0 % curtailment rates). The very low curtailment of Italy in the PCI/PMI infrastructure level (i.e., 0.1 %) is completely removed due to the additional imports from North Africa. The France-South region can benefit from privileged access to Iberian supply. The Netherlands benefit from additional import capacities. Furthermore, Bulgaria, Croatia have high shares of hydrogen produced from natural gas to cover nation demand.

Compared to the PCI/PMI hydrogen infrastructure level, group 2 grows by France and Estonia. Among the countries of group 2, Spain, Sweden and Finland receive a significant share of their supply from national electrolytic hydrogen production, while Belgium, the Netherlands, Austria and Germany have their curtailment reduced thanks to (indirect) access to the extra-EU import capacities in North Africa unlocked in the Advanced level. Austria and Germany have (indirect) access to extra-EU import capacities. France benefits both from Iberian supply as well as imports to countries in its East, Estonia benefits from its proximity to Finland, and Austria benefits from its connections with both Germany and Italy.

Compared to the PCI/PMI hydrogen infrastructure level, group 3 grows by the Poland-North region, Hungary, the Belgium-Mons region, Czechia, Slovakia, the France-Southwest region, and Romania due to non-PCI projects with advanced status that provide additional capacities to supply these countries/regions. Among the countries of group 3, some countries like Denmark, Portugal, the United Kingdom and Ireland, despite having significant electrolytic hydrogen production compared to the national demand, still cannot cover all demand when RES are not available. In the cases of Denmark and Portugal, being peripheral countries, their neighbouring countries (i.e., Germany and Spain) can help to mitigate hydrogen demand curtailment. Lithuania and Latvia can receive hydrogen from Finland via Estonia and from Poland to mitigate demand curtailment. Estonia and Poland will both only provide hydrogen to Lithuania and Latvia when having access to surplus hydrogen quantities. In the case of the United Kingdom and Ireland, being isolated from Europe leads to higher curtailment rates due to limited options for cross-border balancing.

Within the same group 3, Slovakia, Hungary and Romania are benefiting from new interconnections. Thereby, Slovakia is the transit country to Hungary and Hungary is the transit country to Romania. While the France-Southwest region is still isolated and strictly depends on local production, the hydrogen demand curtailment is reduced compared to the PCI/PMI hydrogen infrastructure level. This is enabled by the additional hydrogen storage capacities in the France-Southwest region in the advanced infrastructure level. In addition, Czechia benefits from the fact that its western neighbours can share more hydrogen surplus.

In group 4, Greece shows a curtailment rate of 33.4 %, which can be explained by the fact that despite the new interconnections in the advanced infrastructure level in Eastern Europe, Greece and Bulgaria remained isolated and therefore their situation is not improved compared to the PCI/PMI hydrogen infrastructure level.

Group 5 includes countries with very high curtailment rates. All the countries in this group are fully isolated and rely on national hydrogen supplies mainly produced from natural gas.

Group 6 includes only isolated countries that have hydrogen demand but no national hydrogen production assets connected to Zone 2.

In Denmark, Finland, Ireland, Sweden, and Slovenia, on top of the hydrogen demand curtailments observed in Zone 2 nodes as described in the paragraphs above, hydrogen demand curtailments can be observed in Zone 1. While these curtailments are limited to a few months in Sweden and Finland, it is of relevance in every month in Ireland and reaches high levels in Denmark and Slovenia. Compared to the PCI/PMI hydrogen infrastructure level, these curtailments are slightly reduced due to higher availability of electricity for electrolytic hydrogen production due to additional imports (i.e., new availability of North African imports and import terminals).

6.1.2.3 IGI INDICATOR 2.2: HYDROGEN DEMAND CURTAILMENT FOR STRESSFUL WEATHER YEAR

Threshold 1: Average yearly hydrogen demand curtailment rate above 3 %

Table 20 shows the yearly average hydrogen demand curtailment rates in the Zone 2 nodes of various European countries for 2030, simulated under a stressful weather year. This weather scenario assumes adverse conditions, such as reduced wind and solar energy availability, which directly impacts electrolytic hydrogen production. For countries with

hydrogen markets divided into multiple sub-zones (i.e., nodes), curtailment rates are depicted individually for each sub-zone on the map. The yearly average hydrogen curtailment rates are thereby colour-coded to indicate levels relative to the set threshold 1: blue signifies curtailment above the threshold, while green represents rates that are not.

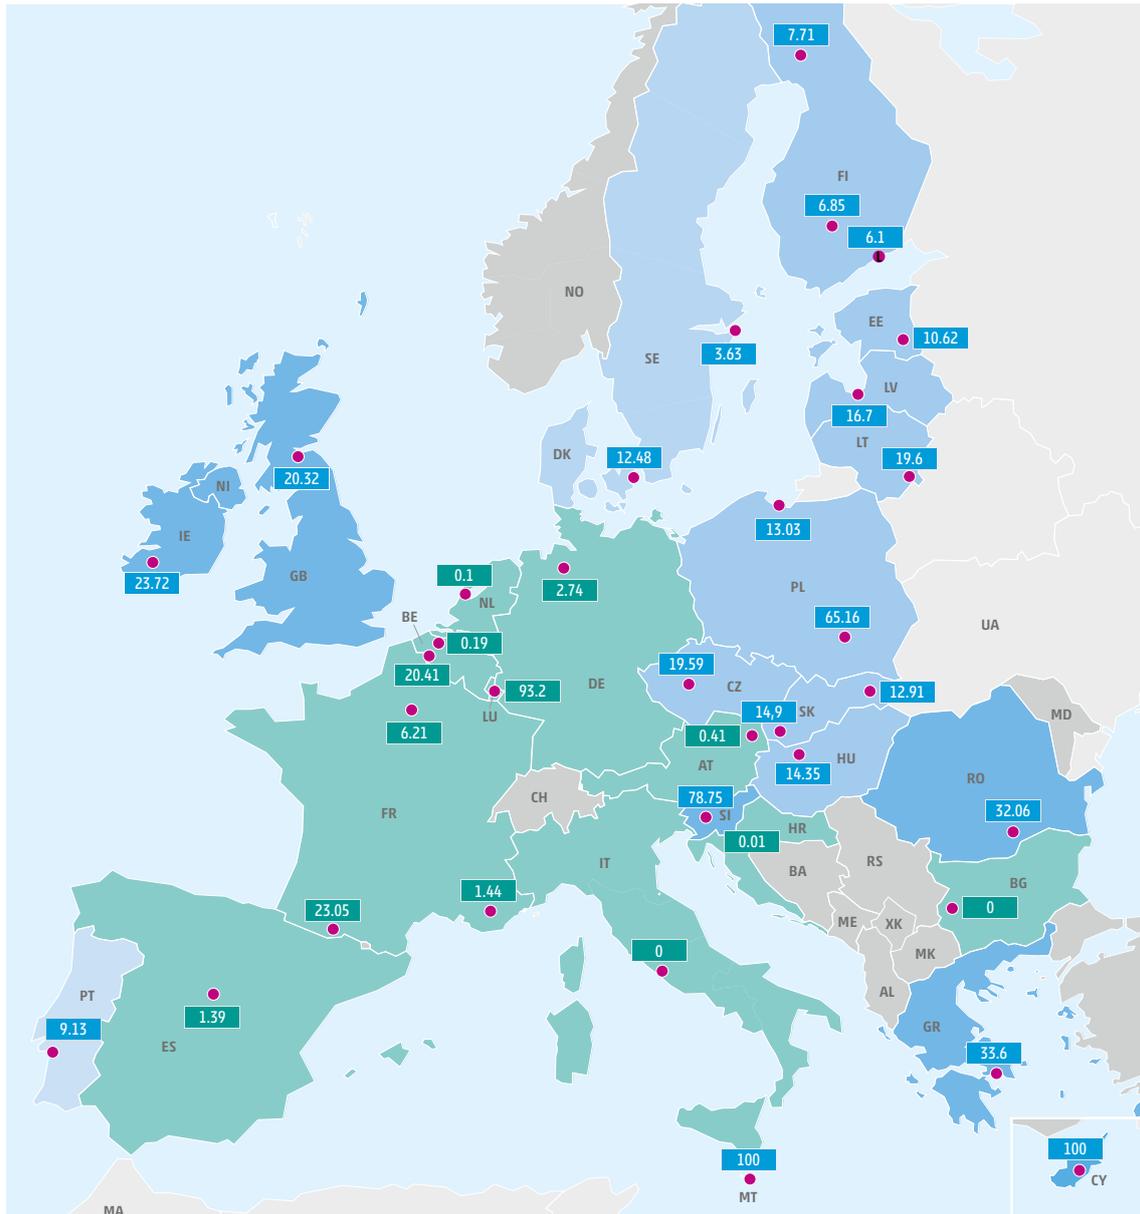

Figure 20: Yearly average hydrogen demand curtailment rate at country or node level in the advanced infrastructure level in 2030 for stressful weather year (unit: %).

In interconnected countries, the average hydrogen demand curtailment rates in Zone 2 are more or less doubled compared to the reference weather

year as less hydrogen is available during stressful weather conditions.

H ₂ Demand Zone	Yearly average curtailment rate (%)	Threshold 1 passed
ATH ₂	0.4	YES
BEh ₂	0.2	NO
BEh ₂ Mo	20.4	YES
BGh ₂	0.0	NO
CYh ₂	100.0	YES

SKh ₂ W	12.9	YES
UKh ₂	20.3	YES

Table 20: Yearly average hydrogen demand curtailment rate at country/sub-zone level in the advanced infrastructure level in 2030 for stressful weather year (unit: %).

As detailed in Table 20, (regions of) countries can be aggregated in different groups according to their average yearly hydrogen demand curtailment rates:

- 1. Rates below 3 %:** Bulgaria, Croatia, Italy, the Netherlands, Belgium, Austria, Germany, Spain France-South region.
- 2. Rates between 3 % and 20 %:** Sweden, France, Denmark, Finland, Poland-North region, Hungary, Latvia, Lithuania, Estonia, Portugal, Czechia, Slovakia.
- 3. Rates between 20 % and 50 %:** Belgium-Mons region, France-Southwest region, Greece Ireland, Romania, the United Kingdom.
- 4. Rates between 50 % and 100 %:** Slovenia, Poland-South region, Luxembourg.
- 5. Full curtailment of 100 %:** Cyprus, Malta. Compared with the PCI/PMI hydrogen infrastructure level, group 1 grows by Germany and Austria, reducing these countries' hydrogen demand curtailment below the threshold of IGI indicator 2.2.

Threshold 2: hydrogen demand curtailment rate of more than 5 % for at least one month per year

All the countries and regions that exceed threshold 1 also exceeded threshold 2.

6.2 COMPARISON BETWEEN PCI/PMI HYDROGEN INFRASTRUCTURE LEVEL AND ADVANCED INFRASTRUCTURE LEVEL

6.2.1 MAXIMUM UTILISATION OF INTERCONNECTIONS

Table 21 displays the maximum utilisation rates of hydrogen interconnections for both hydrogen infrastructure levels in 2030 for the reference weather year. Table 22 shows this information for the stressful weather year.

As stated in section 3, some countries are completely isolated from the hydrogen infrastructure:

- ▲ Countries and regions that are isolated in both hydrogen infrastructure levels: Slovenia, Ireland, the United Kingdom, Cyprus, Malta, France-Southwest region, Poland-South region, Luxembourg, Bulgaria and Greece are interconnected with each other but isolated from the main backbone.

- ▲ Countries that are only isolated in the PCI/PMI hydrogen infrastructure level: Slovakia, Hungary, Romania, Bosnia, Croatia and Poland-North region are interconnected with each other in the Advanced hydrogen infrastructure level but isolated from the main backbone.

When interpreting the tables, the strategic dimensioning of interconnections becomes more evident when also considering the data for 2040 as presented in section 7.2.1. As hydrogen pipelines have significant economies of scale, one early investment with a large pipeline diameter can represent an anticipatory investment.

Interconnection	Stated direction		Reverse direction		Comments
	PCI/PMI IL	ADV IL	PCI/PMI IL	ADV IL	
ATH ₂ → DEh ₂	60	100	48	48	As DZ supply is added in the ADV IL, flows from AT to DE increase as AT has more access to North African H ₂ through Italy
ATH ₂ → IB-ITH ₂	44	9	63	100	As DZ supply is added in the ADV IL, the max. utilisation rate is reached.
ATH ₂ → IB-SKh ₂ W		40		0	As no UA supply is available, AT supplies SK.
BAh ₂ → HRh ₂		0		0	The low utilisation is caused by low hydrogen supply to these jointly isolated countries, so BA and HR always need hydrogen supply themselves if the other country needs it.
BEh ₂ → DEh ₂	85	85	80	80	With additional supply options in ADV IL, DE's dependence on BE's supplies decreases.
BEh ₂ Mo → FRh ₂ Va	0	0	15	15	The flow direction is from FR to BE.
BEh ₂ → NLh ₂	0	0	100	100	The flow direction is from NL to BE.
BGh ₂ → GRh ₂	6	6	8	8	The low utilization is caused by the isolation of these countries along with the relatively low supply of hydrogen
CZh ₂ → DEh ₂	0	0	6	7	The flow direction is from DE to CZ as no UA supply is available.
DEh ₂ → DKh ₂	38	39	67	67	
DEh ₂ → FRh ₂	100	100	100	98	
DEh ₂ → NLh ₂	59	30	73	56	With additional supply options in ADV IL, the offered import flexibilities reduce max. utilisation.
DEh ₂ → PLh ₂ N		100		0	The flow direction is from DE to PL.

Interconnection	Stated direction		Reverse direction		Comments
	PCI/PMI IL	ADV IL	PCI/PMI IL	ADV IL	
DEh ₂ → PLh ₂ nbc	100	76	3	0	The flow direction is from DE to PL. New terminal in PL and new connection from DE to PL (supplied by new supply options) in ADV IL reduce max. utilisation.
DEh ₂ ba → DEh ₂		100			
DEh ₂ bp → DEh ₂ ba		0			
EEh ₂ → Flh ₂ S	46	77	6	6	New terminal in PL and new connection from DE to PL (supplied by new supply options) in ADV IL increase max. utilisation.
EEh ₂ → LVh ₂	5	5	47	78	With additional supply options and connection from DE to PL in ADV IL West of LV, max. utilisation from LV to EE can be increased.
ESh ₂ → FRh ₂ S	95	95	0	83	Capacity from ES to FR-South would be a bottleneck if FR-South to FR was not already restricting flows.
ESh ₂ → PTh ₂	9	9	22	22	
Flh ₂ → Flh ₂ AI	26	17	10	10	
Flh ₂ → Flh ₂ N	0	0	1	1	Very high capacities set in the model as this arc is not representing a bottleneck.
Flh ₂ → Flh ₂ S	0.4	0.3	0.4	0.3	Very high capacities set in the model as this arc is not representing a bottleneck.
Flh ₂ AI → DEh ₂	71	60			Flow direction is from FI to DE.
Flh ₂ AI → SEh ₂	0	6	15	15	
Flh ₂ N → SEh ₂	23	23	10	21	
FRh ₂ → FRh ₂ S	100	100	100	100	Capacity from FR-South to FR is a bottleneck that limits supplies from ES.
FRh ₂ → FRh ₂ Va	15	15	7	7	
HUh ₂ → IB-SKh ₂ C		0		57	Flow direction is SK to HU. The max. utilisation would be higher if there was more hydrogen supply to Europe, allowing SK to transit more hydrogen to HU and downstream countries which remain having HCR.
HUh ₂ → ROh ₂		44		0	Flow direction is HU to RO. The max. utilisation would be higher if there was more hydrogen supply to Europe, allowing HU to transit more hydrogen to RO which remains having high HCR.
IB-ITh ₂ → ITh ₂	0	0	63	84	
IB-SKh ₂ C → SKh ₂ E		3		0	The max. utilisation would be higher if there was more hydrogen supply to Europe as countries in the area remain having HCR.
IB-SKh ₂ C → SKh ₂ W		46		42	The max. utilisation would be higher if there was more hydrogen supply to Europe as countries in the area remain having HCR.
IB-SKh ₂ E → SKh ₂ E		0		0	The max. utilisation would be higher if there was more hydrogen supply to Europe as countries in the area remain having HCR.
IB-SKh ₂ W → CZh ₂		15			SK supplies hydrogen received from AT to CZ.
IB-SKh ₂ W → SKh ₂ W		40		0	The max. utilisation would be higher if there was more hydrogen supply to Europe as countries in the area remain having HCR.
LTh ₂ → LVh ₂	50	81	4	4	With additional supply options and connection from DE to PL in ADV IL West of LT, max. utilisation from LT to LV can be increased.

Interconnection	Stated direction		Reverse direction		Comments
	PCI/PMI IL	ADV IL	PCI/PMI IL	ADV IL	
LTh ₂ → PLh ₂ nb	3	0	52	88	With additional supply options and connection from DE to PL in ADV IL West of LT, max. utilisation from PL to LT can be increased.
PLh ₂ nb → PLh ₂ N	54	23			New terminal in PL-North and new connection from DE to PL (supplied by new supply options) in ADV IL reduce max. utilisation.
DEh ₂ bp → DEh ₂		100			Allows import through DEbp terminal in ADV IL.
DZh ₂ → ITh ₂		26			The max. utilisation is limited by the hydrogen supply potential of DZ as defined in TYNDP 2024 scenarios.
LH ₂ _Tk_BE → BEh ₂	100	100			In PCI/PMI IL, terminal capacities are bottleneck for hydrogen imports as not reaching supply potentials as defined in TYNDP 2024 scenarios. Bottleneck is lifted in ADV IL.
LH ₂ _Tk_DE → DEh ₂	100	100			In PCI/PMI IL, terminal capacities are bottleneck for hydrogen imports as not reaching supply potentials as defined in TYNDP 2024 scenarios. Bottleneck is lifted in ADV IL.
LH ₂ _Tk_DEbp → DEh ₂ bp	0	100			New connection allows utilisation of DEbp terminal in ADV IL.
LH ₂ _Tk_NL → NLh ₂	100	100			In PCI/PMI IL, terminal capacities are bottleneck for hydrogen imports as not reaching supply potentials as defined in TYNDP 2024 scenarios. Bottleneck is lifted in ADV IL.
LH ₂ _Tk_PLN → PLh ₂ N		100			New terminal in ADV IL.

6.2.2 ANALYSIS WITH HYPOTHETICAL INFRASTRUCTURE APPROACH

The main purpose of this section is the investigation of any system limitations due to the potential bottlenecks in the PCI/PMI and Advanced infrastructure levels, without any implications regarding the development of specific projects¹³. It has been found already in the previous sections that infrastructure gaps were identified between Advanced infrastructure level and PCI/PMI infrastructure level. The Advanced infrastructure level is containing all projects presented in the PCI/PMI infrastructure level, as well as additional projects. The Advanced infrastructure level includes all projects presented in the PCI/PMI infrastructure level, as well as additional projects. To explore different possibilities and limitations, four different hypothetical scenarios were defined:

- ▲ **Unlimited Pipes (UP):** unlimited connections between (transmission) nodes;
- ▲ **Unlimited Pipes + Storages (UPS):** unlimited connections between nodes + unlimited storage withdrawal, injection and working gas volume in existing storage countries;
- ▲ **Unlimited Imports (UI):** unlimited imports capacities for imports defined in each infrastructure level and reference years;
- ▲ **Unlimited Storages (US):** unlimited storage withdrawal, injection and working gas volume in existing storage countries;

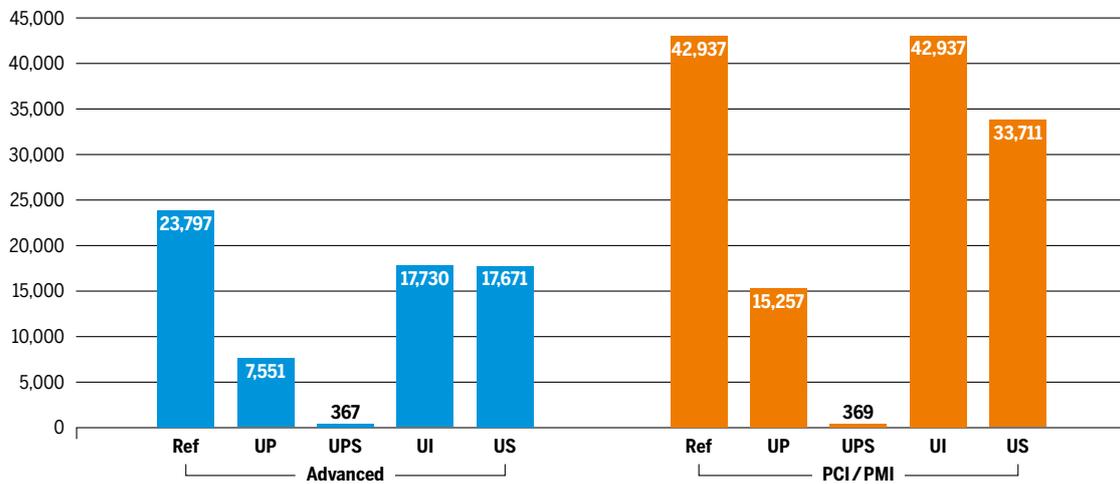

Figure 21: Shortage Advanced level and Shortage PCI/PMI level 2030 (unit: GWh/y).

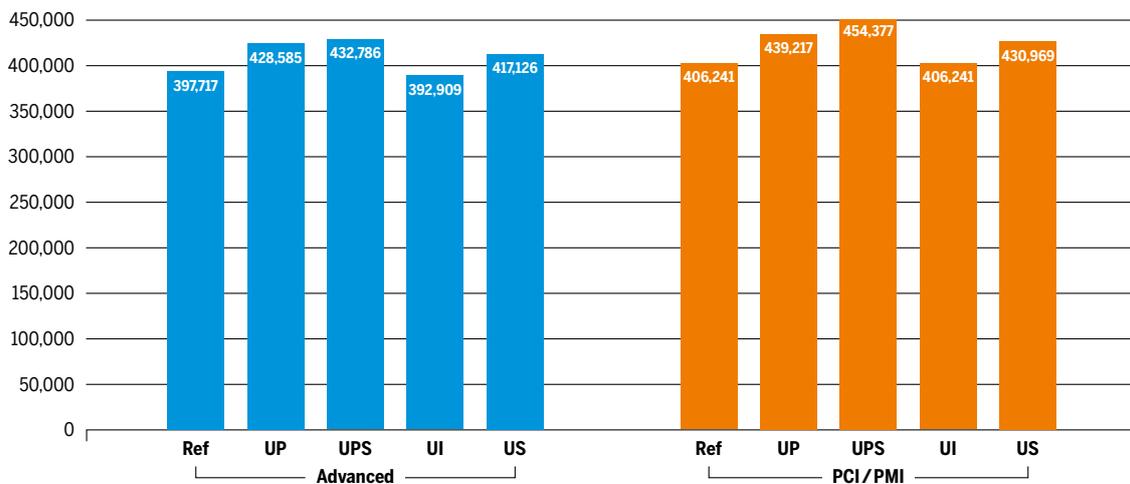

Figure 22: Electrolyser production Advanced level 2030 and PCI level 2030 (unit: GWh/y).

13 See section 6 of Annex D2 - Hydrogen Infrastructure Gaps Identification Methodology, available on <https://tyndp2024.entsog.eu/downloads/>

Under unlimited pipelines scenario, shortage is mitigated in both cases by more than 50%. Internal bottlenecks are depicting limitations to meet the demand and supply. Moreover, adding more flexibility by utilizing storages is reducing almost all curtailment. Thus, additional investments, to enhance interconnections and storages capacities could mitigate curtailment in Europe in 2030.

Moreover, when comparing with the unlimited imports scenario, where it seems to not give much

extra benefits, it confirms that internal bottlenecks are the limitation to enable flow to go from different supply sources to demand.

By comparing the integration of electrolyzers production is evident that the bottlenecks are limiting the integration of power generation in the system.

This integration of electrolyzers production is also valid for all other production sources.

6.2.3 IDENTIFICATION OF PROJECTS THAT SOLVED OR MITIGATED INFRASTRUCTURE GAPS

Solved infrastructure gaps in Advanced hydrogen infrastructure level compared to PCI/PMI hydrogen infrastructure level

The additional projects of the advanced infrastructure level could solve the following indications of regional hydrogen infrastructure gaps:

- ▲ Borders as captured by IGI indicator 1: Hungary-Austria, Hungary-Romania, Hungary-Slovakia, Slovakia-Austria, Slovakia-Czechia.
- ▲ Countries and regions as captured by IGI indicator 2.1: France-South region, the Netherlands.

- ▲ Countries and regions as captured by IGI indicator 2.2: Austria, Germany.

Nevertheless, not all IGI indicators could be solved from a regional perspective even if the advanced hydrogen projects provide benefits.

Identification of advanced, non-PCI/PMI projects responsible for solving hydrogen infrastructure gaps by addressing hydrogen infrastructure bottlenecks

The following advanced, non-PCI/PMI projects contributed to mitigate the identified infrastructure gaps in the 2030 assessment:

- ▲ Pipeline imports
 - North African hydrogen corridor to Italy (North Africa hydrogen corridor)
- ▲ Intra-EU connections:
 - Austria to Slovakia (Slovak Hydrogen Backbone)
 - Netherlands to Germany (H2Coastlink, IP Elten/Zevenaar – Cologne, Hyperlink and H2ercules Network North-West)
 - Germany to Poland (Pomeranian Green Hydrogen Cluster)
 - Slovakia to Hungary (HU/SK hydrogen corridor and SK-HU H₂ corridor)

- ▲ Import terminals
 - New Ammonia terminal in Gdansk and Hydrogen Highway – Northern Section
 - Increased terminal capacity in the Netherlands (Eemshaven H₂)
- ▲ Hydrogen storages
 - Hydrogen storage projects in Germany (RWE H₂ Storage Gronau-Epe, UST Hydrogen Storage Krummhörn, RWE H₂ Storage Xanten, EWE Hydrogen Storage Huntorf, EWE Hydrogen Storage Jemgum, RWE H₂ Storage Staßfurt, EWE Hydrogen Storage Huntorf)
 - Hydrogen storage project in the France-Southwest region (HySoW storage) of France

Besides the projects listed above, the projects included in the PCI/PMI hydrogen infrastructure level also contribute to the solving and mitigation of infrastructure gaps.

7 ASSESSMENT FOR 2040

This section describes the evolution of the IGI indicators for the reference weather year (i.e., 1995) and the stressful weather year (i.e., 2009) for the analysed infrastructure levels (i.e., PCI/PMI and Advanced hydrogen infrastructure levels) for the simulation year 2040.

7.1 INFRASTRUCTURE GAPS IDENTIFICATION

7.1.1 ASSESSMENT OF PCI/PMI HYDROGEN INFRASTRUCTURE LEVEL

High-level results for reference weather year

The overall yearly supply-demand balance for the PCI/PMI hydrogen infrastructure level in 2040 is presented in Table 23. As detailed in Table 23, the overall hydrogen demand triples compared to the 2030 hydrogen demand level, leading to a yearly hydrogen demand of 1936 TWh/y in Europe. Electrolytic hydrogen production remains the main source of hydrogen in Europe, satisfying 56 % of the yearly hydrogen demand of Europe.

Despite i) the infrastructure development foreseen in the PCI/PMI hydrogen infrastructure level for 2040 (see section 3), ii) the increase of extra-EU supply potentials via terminals and pipelines, and iii) the significant increase of electrolytic hydrogen production (by approximately 246 %), this is not sufficient to satisfy the hydrogen demand in many European countries. Therefore, overall hydrogen demand curtailment rises compared to the 2030 values leading to an average hydrogen curtailment rate of 15 % in Europe.

Yearly hydrogen supply-demand balance	PCI/PMI IL 2030	PCI/PMI IL 2040
H ₂ produced via electrolysis	310	1,074
H ₂ produced using natural gas	229	162
H ₂ shipped imports	29	83
H ₂ pipeline imports	0	316
Curtailed H ₂ demand	52	294
H ₂ demand for power production	2	77
Total H₂ demand	620	1,929

Table 23: Supply and demand balance in the PCI/PMI hydrogen infrastructure level in 2030 and 2040 for reference weather year (unit: TWh/y).

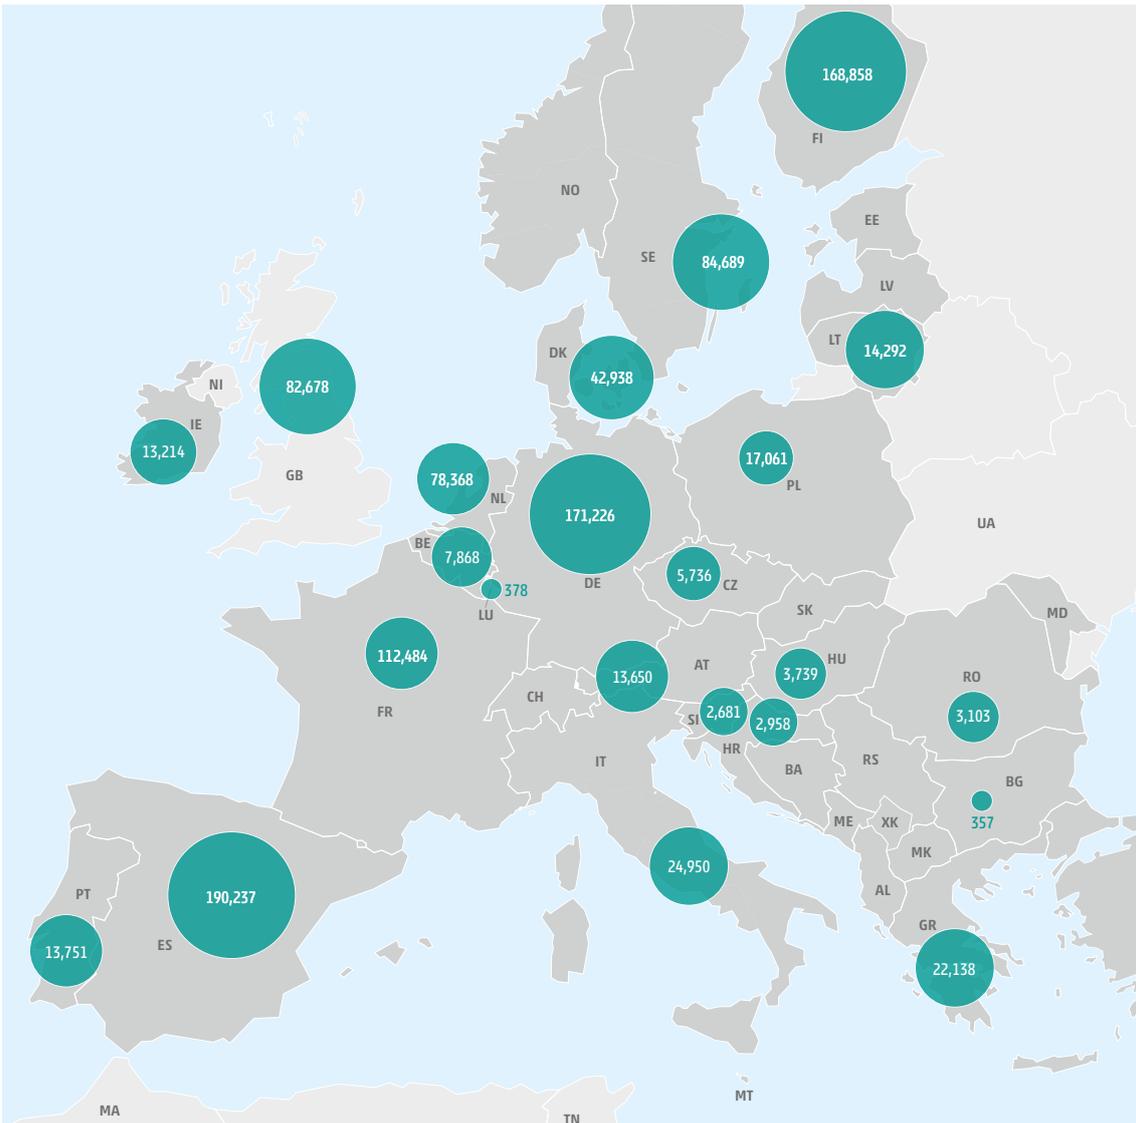

Figure 23: Distribution of electrolytic hydrogen production per country in the PCI/PMI hydrogen infrastructure level in 2040 for reference weather year (unit: GWh/y).

Figure 23 shows the hydrogen production via electrolysis in the different European countries for the PCI/PMI hydrogen infrastructure level in the 2040 assessment. European electrolytic production significantly increased compared to 2030 in most European countries. The countries with the highest electrolytic hydrogen production are: Spain, Germany, Finland, France and Sweden. Some countries have more than one source of electrolytic hydrogen production. This is related to the intra-country assumptions that are detailed in the description of the reference weather year in section 6.1.1.

Figure 24 shows the distribution of hydrogen production from natural gas in 2040. There is a reduction in hydrogen production from natural gas compared to 2030 as presented in Table 23. This reduction is explained by i) the 50 % reduction in the installed capacities for hydrogen production from natural gas as defined in the TYNDP 2024 NT+ scenario, ii) the higher electrolytic production as well as iii) the availability of new hydrogen supplies through imports from North Africa, Norway, Ukraine, and via terminals.

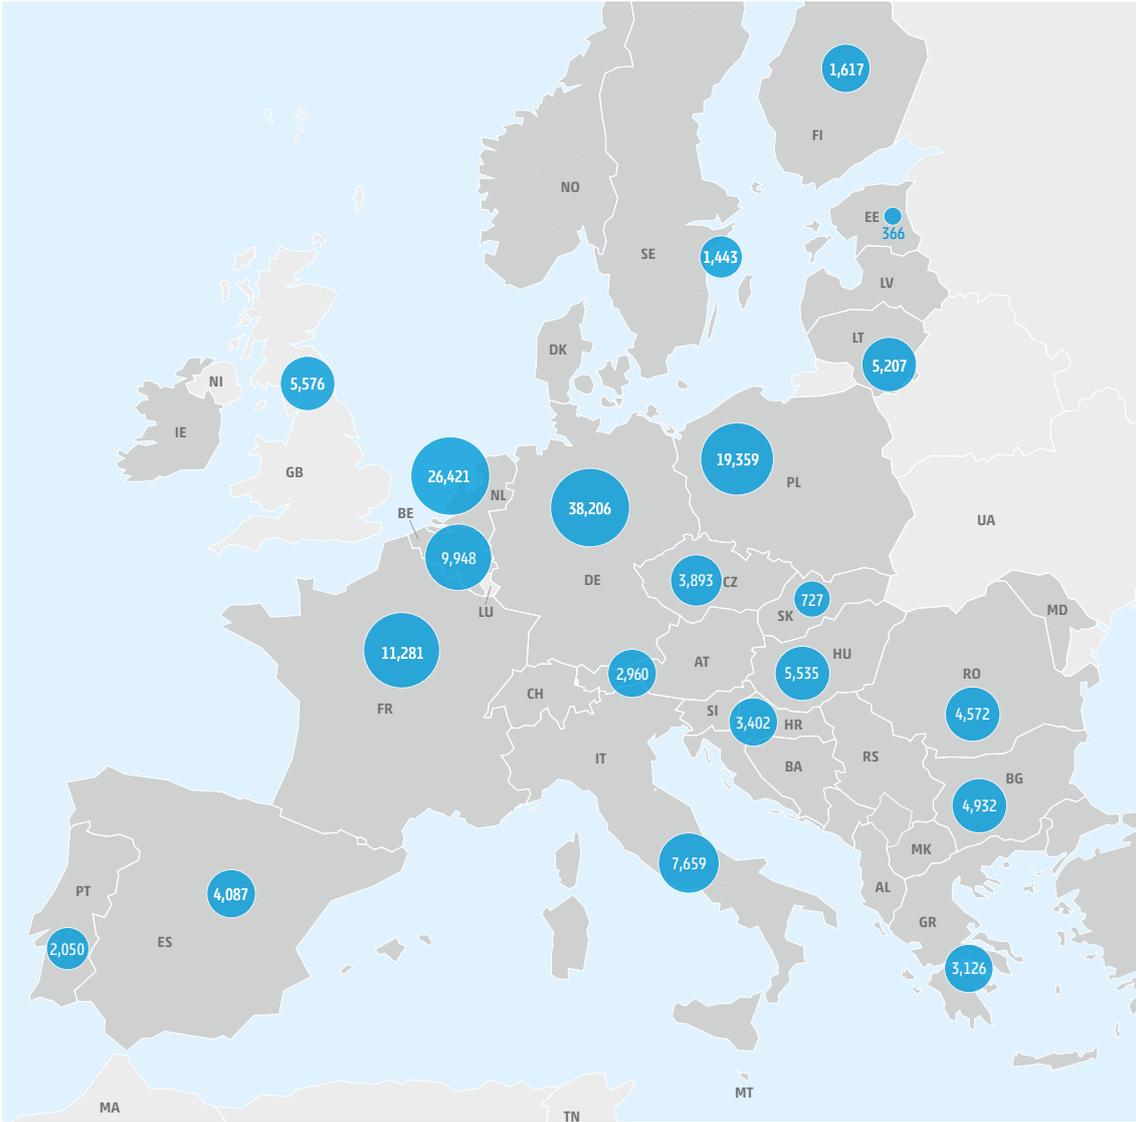

Figure 24: Distribution of hydrogen production from natural gas in the PCI/PMI hydrogen infrastructure level in 2040 for reference weather year (unit: GWh/y).

Country	H ₂ Production via electrolysis	H ₂ Production using natural gas	H ₂ extra-EU imports by pipeline & ship	H ₂ demand

Table 24: Distribution of hydrogen production, imported hydrogen and demand per country in the PCI/PMI hydrogen infrastructure level in 2040 for reference weather year (unit: GWh/y).

Considering the supply and demand distribution presented in Table 24, the intra-EU transport corridors that already emerged in 2030, connecting the electrolytic hydrogen supply produced in the Iberian Peninsula and in the Nordic countries with the main European hydrogen hub in Germany, are even more needed in the 2040 PCI/PMI assessment due to the increase of hydrogen demand between 2030 and 2040. The Iberian corridor is thereby supported by imports from Morocco.

In addition, as presented in Figure 25, other intra-EU transport corridors emerge, mainly driven by the availability of extra-EU supplies in the 2040 assessment. Namely, the new corridors identified for 2040 are:

- ▲ North African corridor, transporting Algerian supplies to Italy, Austria, Germany and other countries.
- ▲ Norwegian corridor, transporting Norwegian supplies to Germany.
- ▲ Ukrainian corridor, transporting Ukrainian supplies to Slovakia and Czechia and other countries.

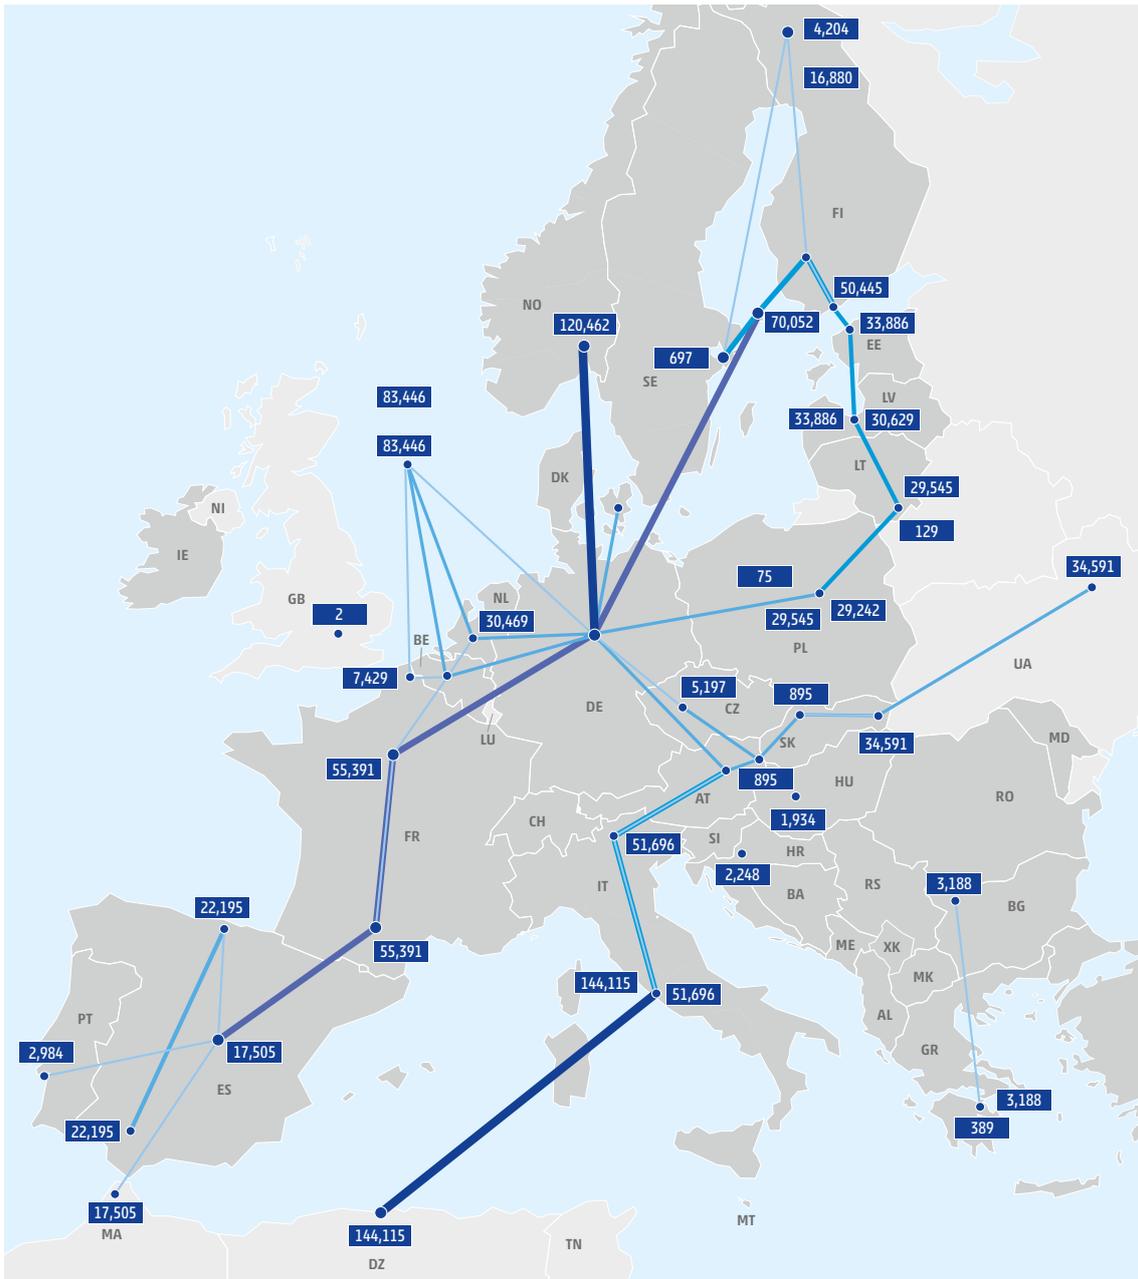

Figure 25: Grid flows* in the PCI/PMI hydrogen infrastructure level in 2040 for reference weather year (unit: GWh/y).

* Grid flows refer to simulations results and do not intend to represent how the European infrastructure is expected to evolve in the simulated years, being just outcomes of a modelling tool. The values are provided as a table in Annex II and as monthly values in Annex III).

In the 2040 PCI/PMI hydrogen infrastructure level assessment for the reference weather year, countries can be grouped in four different categories according to their supply-demand balance on a yearly basis:

1. **Countries which export more than they import:** Sweden, Finland, Denmark, Spain and Greece.
2. **Countries that import more than they export:** Poland, Bulgaria and Portugal.
3. **Transit countries that import more than they consume:** Italy, Germany, Slovakia, Austria, Estonia, Latvia, Lithuania, France and Netherlands.
4. **Isolated countries:** the United Kingdom, Ireland, Luxembourg, Hungary, Romania, Slovenia, Croatia, Malta, Cyprus, Switzerland¹⁴ and the cluster Bulgaria-Greece.

14 IGI report does not consider hydrogen demand in Switzerland (based on TYNDP 2024 Draft Scenario report). However, there is no hydrogen infrastructure connecting Switzerland to any of its European neighbouring countries in the assessed infrastructure levels.

While on a yearly basis some countries are net exporters and some countries are net importers, net exporters may be relying on net imports during certain shorter periods of time and net importers may be providing net exports during certain shorter

periods of time. This can result in bidirectional flows at interconnections. This situation is caused by the seasonality of electrolytic hydrogen production and to some extent by the seasonality of hydrogen demand.

High-level results for stressful weather year

The overall yearly supply-demand balance for the PCI/PMI hydrogen infrastructure level in 2040 for the stressful weather year is presented in Table 25. As detailed in Table 25, electrolytic hydrogen production is the main source of hydrogen in Europe but it is reduced in comparison with the reference weather year. To compensate the reduction of electrolytic hydrogen production, hydrogen import

sources, both via ship and pipeline, increase in comparison with the reference weather year. The imports via terminals increase by 15 %. The consideration of a stressful weather year leads to an approximate rate of 18 % of hydrogen demand curtailment at European level. This represents an increase by 3 % in comparison with the reference weather year.

Yearly hydrogen supply-demand balance	PCI/PMI IL 2030	PCI/PMI IL 2040
H ₂ produced via electrolysis	270	1,000
H ₂ produced using natural gas	245	165
H ₂ shipped imports	36	96
H ₂ pipeline imports	0	320
Curtailed H ₂ demand	69	352
H ₂ demand for power production	2	75
Total H₂ demand	619	1,933

Table 25: Supply and demand balance in the PCI/PMI hydrogen infrastructure level in 2030 and 2040 for stressful weather year (unit: TWh/y).

Figure 26 shows the distribution of hydrogen production via electrolysis in the different European countries for the PCI/PMI hydrogen infrastructure level in the 2040 assessment under stressful weather conditions. Despite the overall reduction of electrolytic hydrogen production, under stressful weather conditions the countries with the highest electrolytic hydrogen production follow the same

distribution as in the PCI/PMI 2040 assessment for the reference weather year (see Figure 23). Some countries have more than one source of electrolytic hydrogen production. This is related to the intra-country assumptions that are detailed in the description of the reference weather year in section 6.1.1.

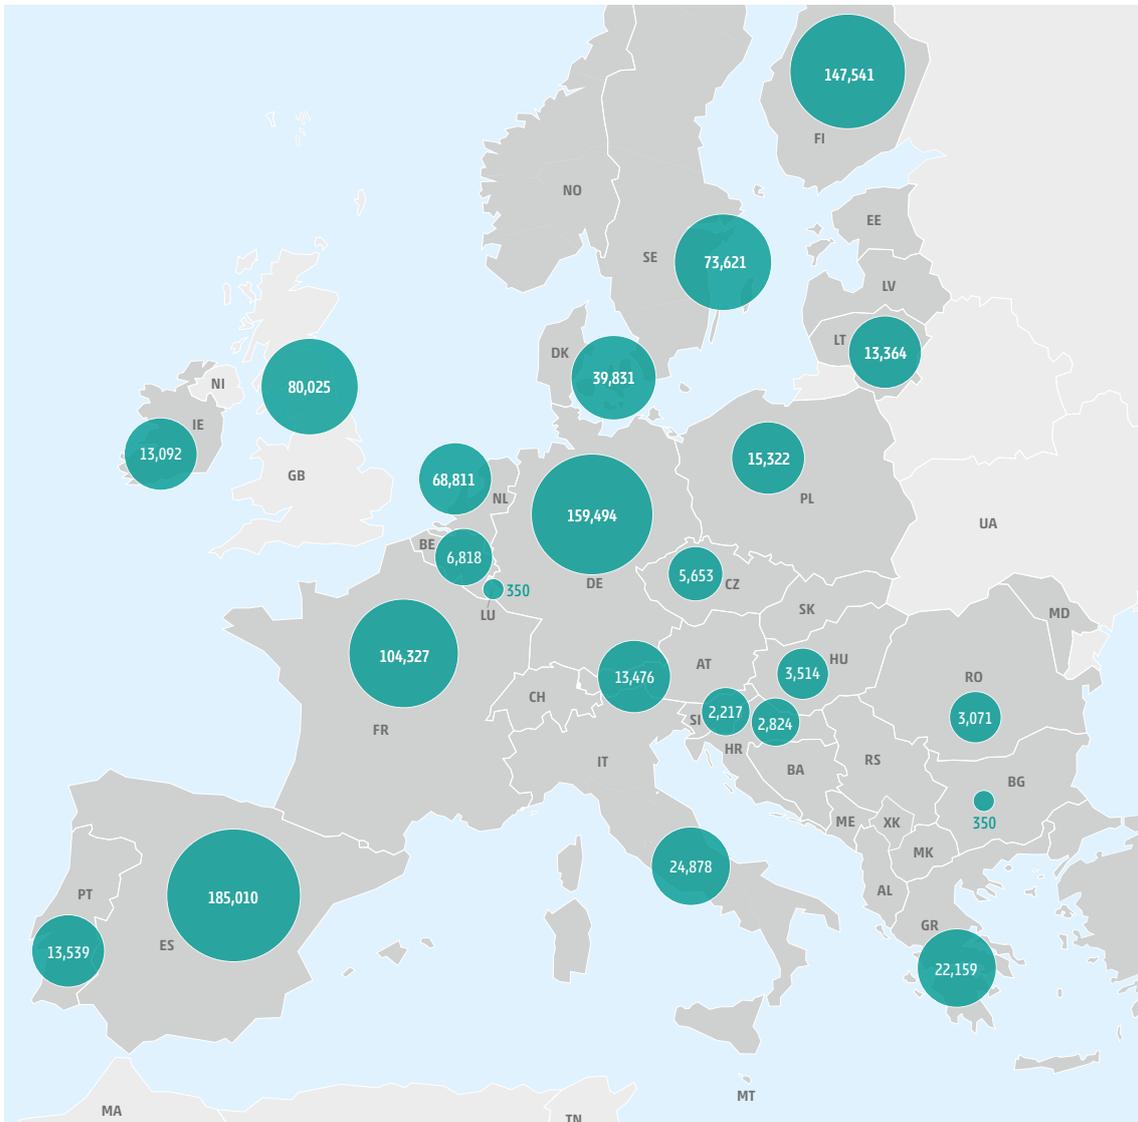

Figure 26: Distribution of hydrogen production via electrolysis in the PCI/PMI hydrogen infrastructure level in 2040 for stressful weather year (unit: GWh/y).

The distribution of hydrogen production produced from natural gas in the different European countries for the PCI/PMI hydrogen infrastructure level in the 2040 assessment under stressful weather conditions is presented in Figure 27. No significant change was observed in comparison to the reference weather year presented in Figure 24.

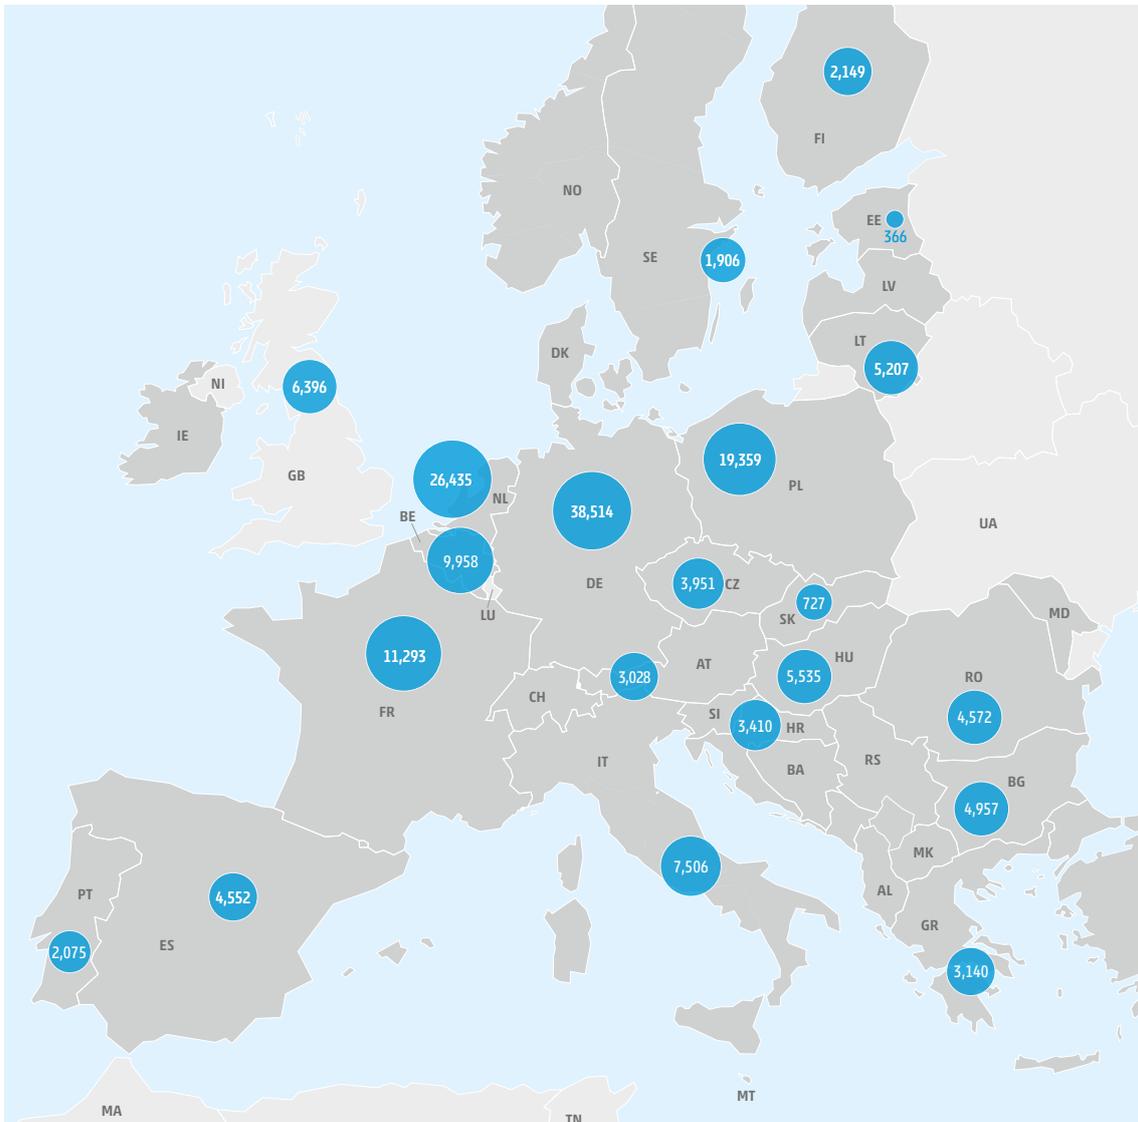

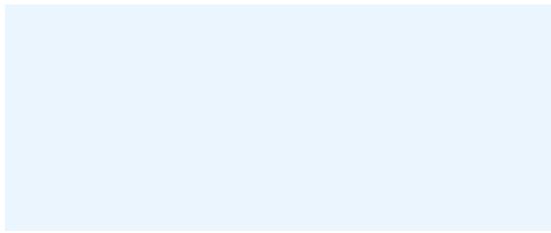

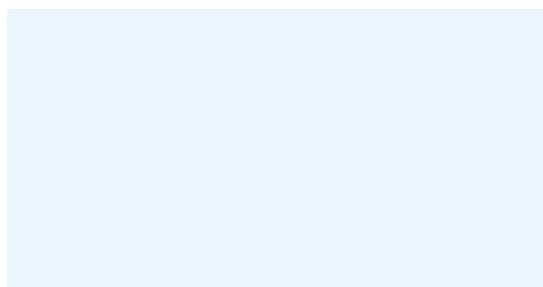

Figure 27: Distribution of hydrogen production from natural gas in the PCI/PMI hydrogen infrastructure level in 2040 for stressful weather year (unit: GWh/y).

Table 26: Distribution of hydrogen production, imported hydrogen and demand per country in the PCI/PMI hydrogen infrastructure level in 2040 for stressful weather year (unit: GWh/y).

As presented in Figure 28 and Table 26 the flows through the two corridors connecting electrolytic supply with German and European demand reduced in the stressful weather year assessment, driven by the overall reduction of available RES. This affects the Iberian and the Nordic corridor. The flows through intra-EU transport corridors that are supplied by Norway, North Africa and Ukraine therefore increase if possible.

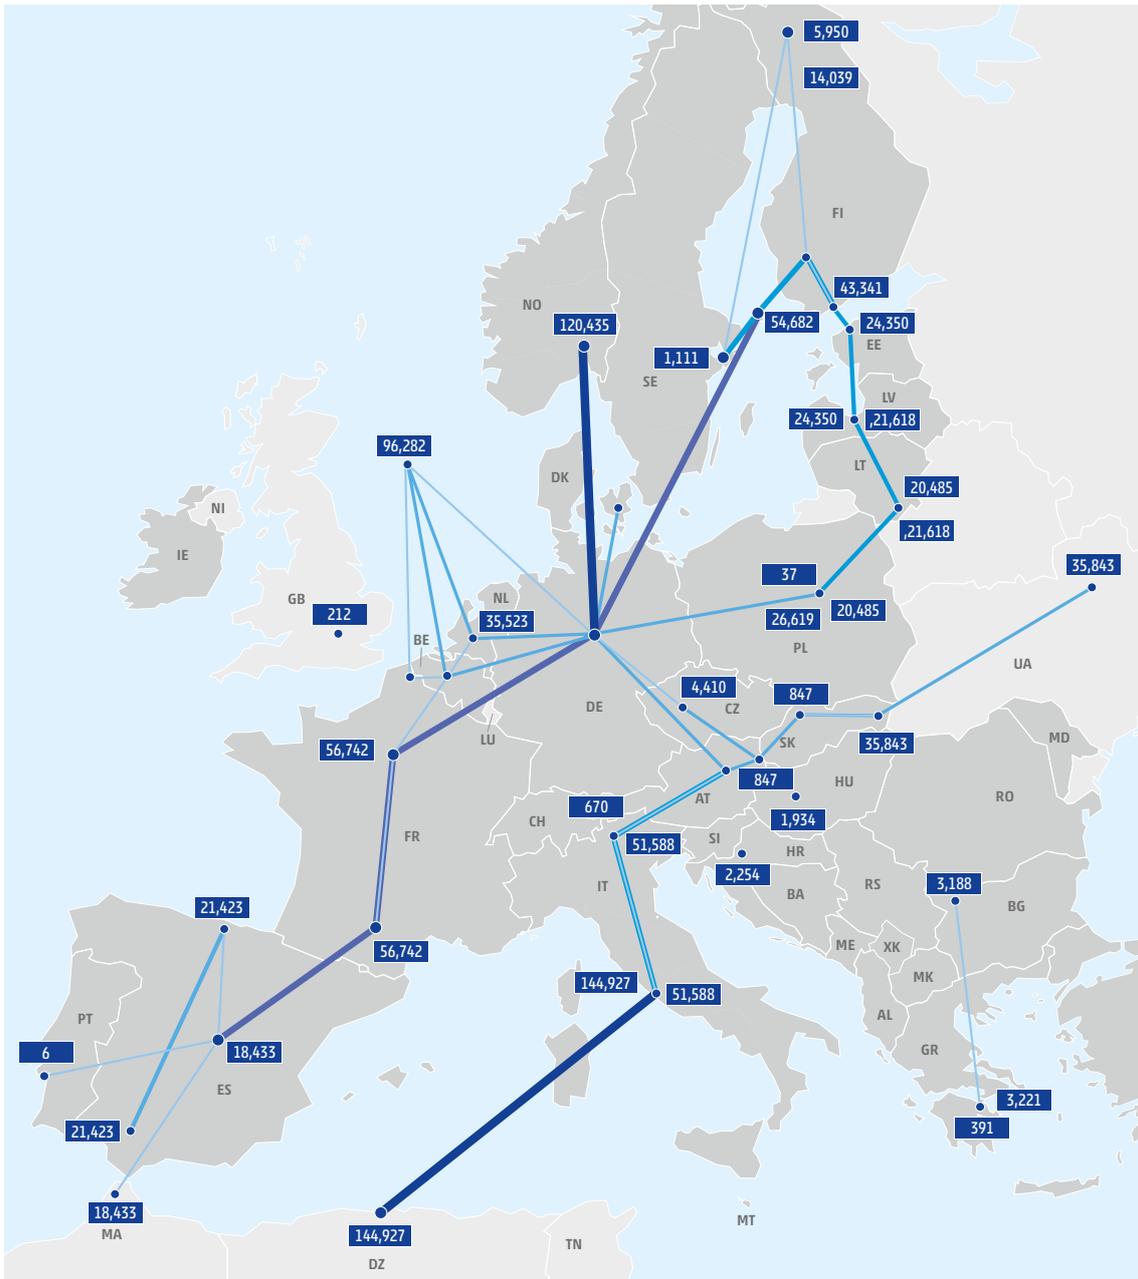

Figure 28: Grid flows* in the PCI/PMI hydrogen infrastructure level in 2040 for stressful weather year (unit: GWh/y).

* Grid flows refer to simulation results and do not intend to represent how the European infrastructure is expected to evolve in the simulated years, being just outcomes of a modelling tool. The values are provided as a table in Annex II and as monthly values in Annex III).

When comparing Figure 28 with Figure 25, most European countries show the same behaviour in terms of being a net exporter, a net importer or a transit country for the stressful as for the reference weather year. As expected under stressful climatic conditions, corridors based mainly on electrolytic production will see their exporting role slightly reduced due to the lower availability of RES (i.e., Iberian and Nordic corridors).

Consequently, also the transit through countries along these routes is reduced (e.g., transit through Baltic countries). On the contrary, both liquid imports and import corridors via pipeline, will maximize their flows to compensate the reduction on European electrolytic supplies.

7.1.1.1 IGI INDICATOR 1: HYDROGEN MARKET CLEARING PRICE SPREADS FOR REFERENCE WEATHER YEAR

Overview: Hydrogen market clearing prices per country

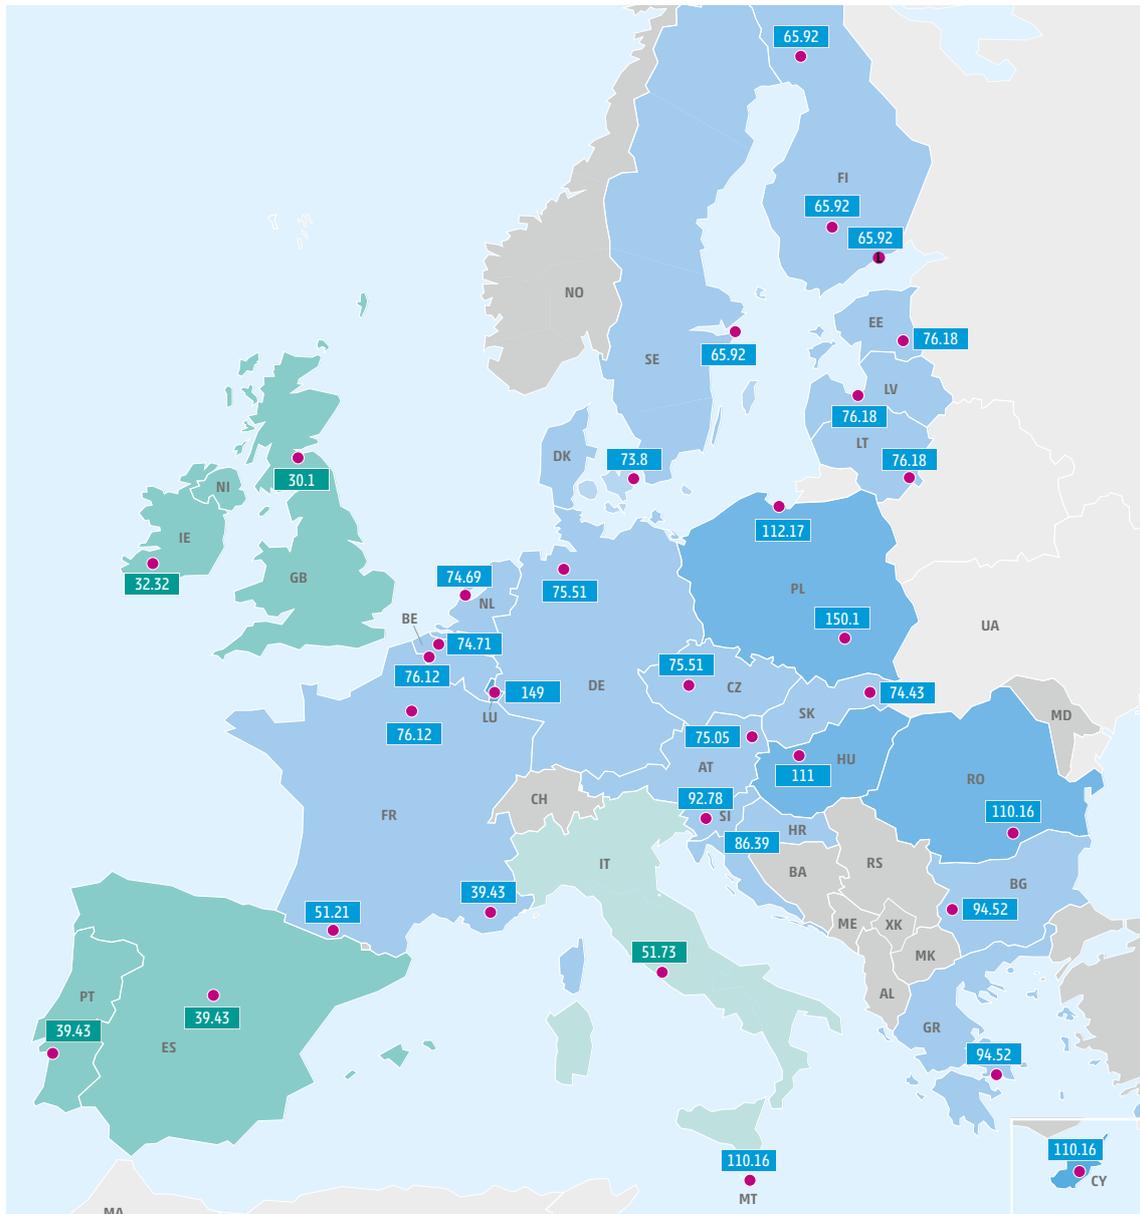

Figure 29: Average of the hourly hydrogen market clearing prices per country in the PCI/PMI hydrogen infrastructure level in 2040 (unit: €/MWh).

The increase of hydrogen demand considered in the 2040 assessment leads to a general increase of average hydrogen market clearing prices in Europe when compared to the 2030 assessment, as represented in Figure 29. This increase is connected to the higher rates of curtailed demand across Europe, and to a lesser extent to the use of more expensive hydrogen import sources to satisfy the hydrogen demand in the different European countries. In South-Eastern Europe, where most of the countries have limited connection to the European hydrogen network and rely on the local hydrogen

production, the increase of hydrogen prices is more pronounced. This steep increase is explained by the increase of demand curtailment, as well as the use of more expensive hydrogen sources to satisfy hydrogen demand in order to avoid curtailment. As presented in Figure 29, this is particularly important as these countries are isolated in the PCI/PMI hydrogen infrastructure level. In addition, the cost of hydrogen production from natural gas increases significantly in the 2040 assessment due to the increase of the ETS price as stipulated in the TYNDP 2024 NT+ scenario.

Despite the increase of hydrogen market clearing prices in many countries in the 2040 assessment, there are other countries or areas where the average hydrogen market clearing price decreases compared to 2030:

- ▲ Due to higher availability of electrolytic hydrogen production: Spain, Portugal, France-South region, Finland, Sweden, the United Kingdom, Ireland.
- ▲ Due to new interconnections:
 - Italy, mainly driven by the availability of North African hydrogen supplies.
 - Slovakia, mainly driven by the connection to the European hydrogen network and the availability of Ukrainian hydrogen supplies.

The price formation in the DHEM is based on the merit order of hydrogen production (see section 4.1). Several price groups stand out, while a significant correlation is understood here as a correlation above 0.7:

- 1. Portugal, Spain, France-South region:** Portugal and Spain are producers and net exporters of electrolytic hydrogen from RES to other countries. While the France-South region is sufficiently connected to the Iberian peninsula, price spreads appear with other groups of (regions of) countries due to an internal bottleneck in France. The prices in this group show no significant correlation with the prices in other groups.
- 2. France-Southwest region:** The prices in this group show no significant correlation with the prices in other groups. The group exists due to bottlenecks within France.
- 3. France-North region:** The prices in this group show significant correlations with prices in groups 4, 5, 6, 7, 11, 12. The group exists due to bottlenecks within France.
- 4. France, Belgium-Mons region:** The prices in this group show significant correlations with prices in groups 3, 5, 7, 10, 11, 12. The group exists due to bottlenecks within France and Belgium.
- 5. Belgium, the Netherlands:** The prices in this group show significant correlations with prices in groups 3, 4, 7, 10, 11, 12. The group exists due to bottlenecks with France and Germany.
- 6. Denmark:** The prices in this group show significant correlations with prices in groups 3, 4, 5, 7, 10, 11, 12. The group exists due to a bottleneck from Denmark to Germany.
- 7. Germany, Czechia, Austria:** Well interconnected countries. The prices in this group show significant correlations with prices in groups 3, 4, 5, 6, 10, 11, 12.
- 8. Italy:** While being connected to Austria, the bottleneck between Italy and Austria is so dominant that Italy has no significant price correlation with any other (region of a) country.
- 9. Poland-North region:** While being connected to Germany and Lithuania (via the Nordic-Baltic Hydrogen Corridor), the Poland-North region has no significant price correlation with any other (region of a) country due to the bottlenecks associated with both connections.
- 10. Sweden, Finland:** The prices in this group show significant correlations with prices in groups 3, 4, 5, 6, 7, 11, 12. The group exists due to a bottleneck between Sweden/Finland and Germany and a bottleneck between Finland and Estonia.
- 11. Estonia, Latvia, Lithuania:** The prices in this group show significant correlations with prices in groups 3, 4, 5, 6, 7, 10, 12. The group exists due to a bottleneck between Finland and Estonia as well as bottlenecks from Lithuania to Poland and within Poland.
- 12. Slovakia:** The prices in this group show significant correlations with prices in groups 3, 4, 5, 6, 7, 10, 11. The group exists due to a bottleneck from Austria to Slovakia and a bottleneck from Slovakia to Czechia.
- 13. Ireland, the United Kingdom:** Isolated countries without significant price correlations but with average prices below 100 €/MWh.
- 14. Greece, Bulgaria:** Countries showing significant price correlation, jointly isolated from the other European countries.
- 15. Romania, Hungary:** The group exists due to a bottleneck between Slovakia and Hungary (and no connection between Romania and Bulgaria).
- 16. Croatia (only connected to Bosnia), Slovenia, Luxembourg, Cyprus, Malta, Poland-South region:** Isolated countries without significant price correlations (except for Croatia and Slovenia due to a similar national hydrogen production constellation) and with average prices above 100 €/MWh.

The price correlations listed above are enabled by the infrastructure projects already considered in this hydrogen infrastructure level. However, price differences that led to the identification of the groups listed above are not necessarily describing an infrastructure gap. For this identification of infrastructure gaps, the thresholds of IGI indicator 1 are used.

The IGI indicator 1 reveals in the 2040 assessment of the PCI/PMI hydrogen infrastructure level an increase of the price spreads at many European borders when compared to the 2030 assessment.

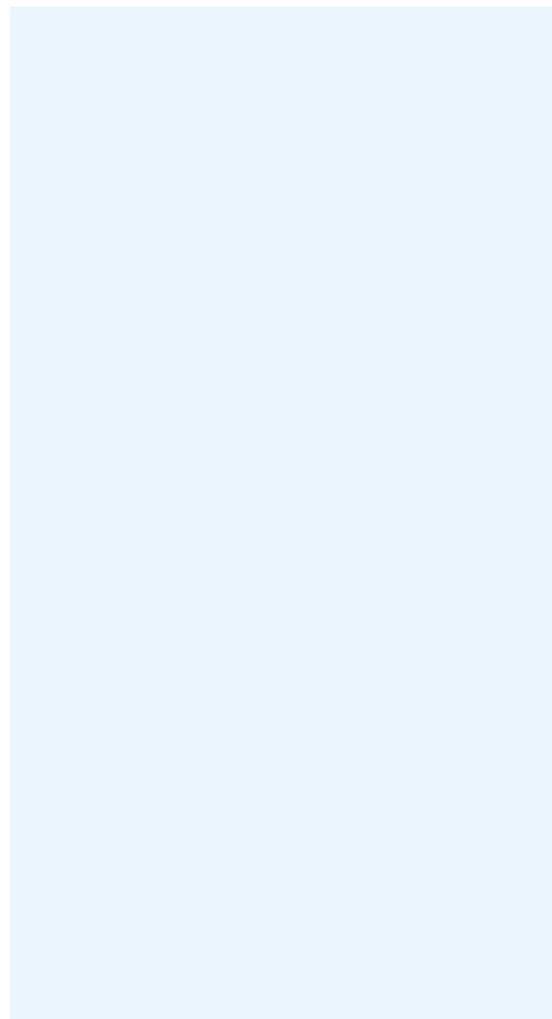

At the following borders, IGI indicator 1 identified additional significant price spreads in comparison with the 2030 assessment due to bottlenecks:

- ▲ Finland/Sweden and Germany: With the increase of electrolytic hydrogen production in Finland and Sweden, market clearing prices are reduced in these countries and the utilisation of the transport route to Germany increases. Thereby, the interconnection acts as a bottleneck.
- ▲ Finland and Estonia: With the increase of electrolytic hydrogen production in Finland, the utilisation of the interconnection between Finland and Estonia increases. Thereby, the interconnection acts as a bottleneck.
- ▲ Italy and Austria (and France and Germany): The availability of Algerian imports significantly increases the utilization of the Italy-Austria-Germany route. Thereby, the interconnection between Italy and Austria acts as a bottleneck. Besides, the hydrogen market clearing price spread between Italy on the one side and Germany or France on the other side is increasing over the threshold. No direct connection between Italy and Germany or France is available.
- ▲ Germany and Poland-North region: The net demand increase in the Poland-North region increases the utilisation of the interconnection between them. Thereby, the interconnection acts as a bottleneck.
- ▲ Lithuania and Poland-North region: The net demand increase in the Poland-North region increases the utilisation of the interconnection between them (via the Nordic-Baltic Hydrogen Corridor). Thereby, the interconnection acts as a bottleneck.

In the 2040 PCI/PMI assessment, there are some borders where the price spread has decreased compared to the 2030 assessment. At the following borders, the IGI indicator 1 therefore does not identify a significant price spread anymore:

- ▲ Slovakia, Austria, Czechia: The connection of Slovakia in the 2040 PCI/PMI hydrogen infrastructure level to Austria and Czechia allows the market clearing prices to converge in these countries.

Countries and regions that are isolated in 2040 in the PCI/PMI hydrogen infrastructure level, such as Hungary, Romania, cluster Greece-Bulgaria, Slovenia, Croatia, Luxembourg, Poland South, France South West, Ireland, the United Kingdom, Malta and Cyprus, remain showing significant price spreads with their neighbouring countries and regions, as identified by IGI indicator 1 in Table 27.

7.1.1.2 IGI INDICATOR 2.1: HYDROGEN DEMAND CURTAILMENT FOR REFERENCE WEATHER YEAR

As explained in section 4.2, this IGI indicator assesses infrastructure gaps by quantifying hydrogen demand curtailments at individual nodes during the reference weather year, assuming no disruptions of infrastructures or of supply sources. It involves a multi-step simulation process integrating DHEM and DGM¹⁵ outputs to evaluate the combined curtailments across nodes. The assessment is performed for the PCI/PMI hydrogen infrastructure level in 2040, showing the effects of matured infrastructure in 2040.

Figure 30 and Table 28 show yearly average curtailment rates of hydrogen demand in the Zone 2 nodes of different European countries. For countries where the hydrogen market is divided into several sub-zones (i.e., nodes), the curtailment rate in the different sub-zones is presented. The yearly average hydrogen curtailment rates are thereby colour-coded in the map to indicate levels relative to the set threshold: blue signifies curtailment above the threshold, while green represents rates that are not above it.

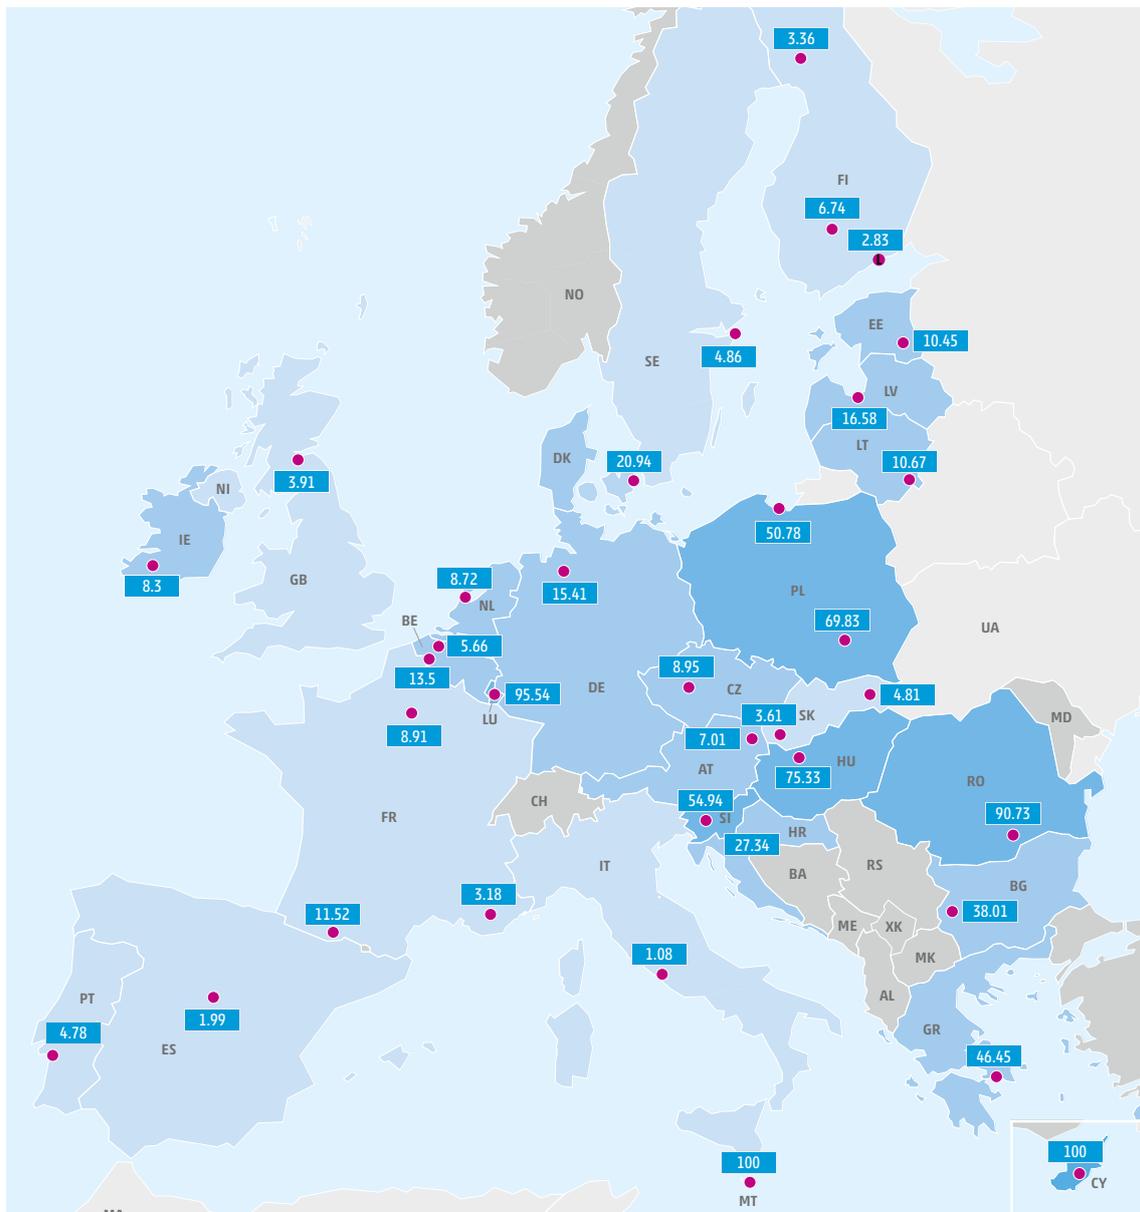

Figure 30: Yearly average hydrogen demand curtailment rate at country or node level in the PCI/PMI hydrogen infrastructure level in 2040 for reference year (unit: %).

¹⁵ This draft TYNDP 2024 IGI report only includes the simulation results of the DHEM.

Node	Demand curtailment rate (%)	Node	Demand curtailment rate (%)
ATH ₂	7.01	HUH ₂	75.33

HRh ₂	27.34		

Table 28: Yearly average hydrogen demand curtailment rate at country/sub-zone level in the PCI/PMI hydrogen infrastructure level in 2040 for reference weather year (unit: %).

All European countries and regions overshoot the threshold of 0 % of IGI indicator 2.1 in the PCI/PMI hydrogen infrastructure level in 2040. However, differences in the hydrogen curtailment rates between nodes are related to the level of infrastructure development and supply availability. In comparison with IGI indicator 1, this IGI indicator focusses on the availability of supplies.

As detailed in Table 28, (regions of) countries can be aggregated in different groups according to their average yearly hydrogen demand curtailment rates:

- 1. Rates below 5 %:** Portugal, Spain, Italy, the United Kingdom, Sweden, Finland-North region, Finland-South region, France-South region, Slovakia-West region, Slovakia-East region.
- 2. Rates between 5 % and 20 %:** Finland, Austria, Belgium, Belgium-Mons region, Czechia, Germany, Estonia, France, France-Southwest region, Ireland, Lithuania, Latvia, the Netherlands.
- 3. Rates between 20 % and 50 %:** Bulgaria, Denmark, Greece, Croatia.
- 4. Rates between 50 % and 100 %:** Slovenia, Romania, Poland-North region, Poland-South region, Hungary, Luxembourg.
- 5. Full curtailment of 100 %:** Cyprus, Malta.

Without the infrastructure already considered in the hydrogen infrastructure level, the overall hydrogen demand curtailment would be higher.

Even though the threshold has been surpassed, countries and regions of group 1 exhibit hydrogen demand curtailment rates below 5 % average yearly curtailment rate, meaning that for a large share of the year their demand is fully covered. Portugal, Slovakia and the United Kingdom show decreased curtailment rates compared to the PCI/PMI hydrogen infrastructure level assessment for 2030. This is particularly evident for Slovakia due to its connection to the European backbone and to Ukrainian hydrogen supplies in 2040. For the other countries and regions in this group, hydrogen curtailment rates increase with the general trend of increased hydrogen curtailment rates in 2040. The primary driver behind this increase is the rising demand for hydrogen within these individual countries, which surpasses the current capacity of available infrastructure. Despite advancements in PCI/PMI hydrogen infrastructure level, the rapid growth in hydrogen consumption highlights the need for further investment and development to meet the increasing demand. This trend underlines the evolving challenges of balancing infrastructure enhancements with accelerating demand.

Group 2 of countries and regions also contains those that show decreased hydrogen curtailment rates, i.e., Austria, the Belgium-Mons region, Czechia, the France-Southwest region, Ireland, Lithuania, and Latvia. Additionally, countries such as Lithuania and France not only benefit from improved import infrastructure but also experience increased their electrolytic production in 2040, which further mitigates curtailment rates. These developments highlight the effectiveness of infrastructure expansion and technological advancements in reducing hydrogen demand curtailment. At the same time, there is slight increases of hydrogen curtailment rates in Germany, Finland and France caused by increases of hydrogen demand in 2040.

Group 3, comprising Bulgaria, Denmark, Greece and Croatia, shows demand curtailments greater than 20 % but below 50 %. Within this category, curtailment rates are observed to rise from 2030 to 2040, driven by the increase of hydrogen demand in these countries and limited cross-border interconnections. The growing demand outpaces infrastructure improvements, leaving national markets unable to fully satisfy their hydrogen demand.

Group 4, experiencing hydrogen demand curtailment rates exceeding 50 % but remaining below

100 %, includes Slovenia and Romania, which have managed to reduce their hydrogen curtailment rates compared to 2030 while remaining isolated. Slovenia achieves a notable reduction from 76.6 % to 54.9 %, whereas Romania shows only a marginal reduction of 0.2 %. Conversely, the Poland-North region, the Poland-South region and Hungary experience increases in hydrogen demand curtailment rates, as significant growth in national demand outstrips the available capacity of the PCI/PMI hydrogen infrastructure as well as hydrogen production options in 2040. Luxembourg remains as isolated in 2040 as in 2030 in the PCI/PMI hydrogen infrastructure level.

Finally, Malta and Cyprus, due to their geographically isolated locations, continue to experience a demand curtailment of 100 % at the PCI/PMI hydrogen infrastructure level in 2040. The absence of connections with broader European hydrogen infrastructure underscores the challenges faced by island nations in integrating into the continental hydrogen network.

In the Poland-North Region, France and Czechia, on top of the curtailments observed in Zone 2 nodes as described in the paragraphs above, hydrogen demand curtailments can be observed in Zone 1 that increase during the winter months.

7.1.1.3 IGI INDICATOR 2.2: HYDROGEN DEMAND CURTAILMENT FOR STRESSFUL WEATHER YEAR

Threshold 1: A yearly average hydrogen demand curtailment rate of more than 3 %

Figure 31 and Table 29 show the yearly average hydrogen demand curtailment rates in the Zone 2 nodes of various European countries for 2040, simulated under a stressful weather year. This weather scenario assumes adverse conditions, such as reduced wind and solar energy availability, which directly impacts hydrogen production. For countries

with hydrogen markets divided into multiple sub-zones (i.e., nodes), curtailment rates are depicted individually for each sub-zone on the map. The yearly average hydrogen curtailment rates are thereby colour-coded to indicate levels relative to the set threshold 1: blue signifies curtailment above the threshold, while green represents rates that are not.

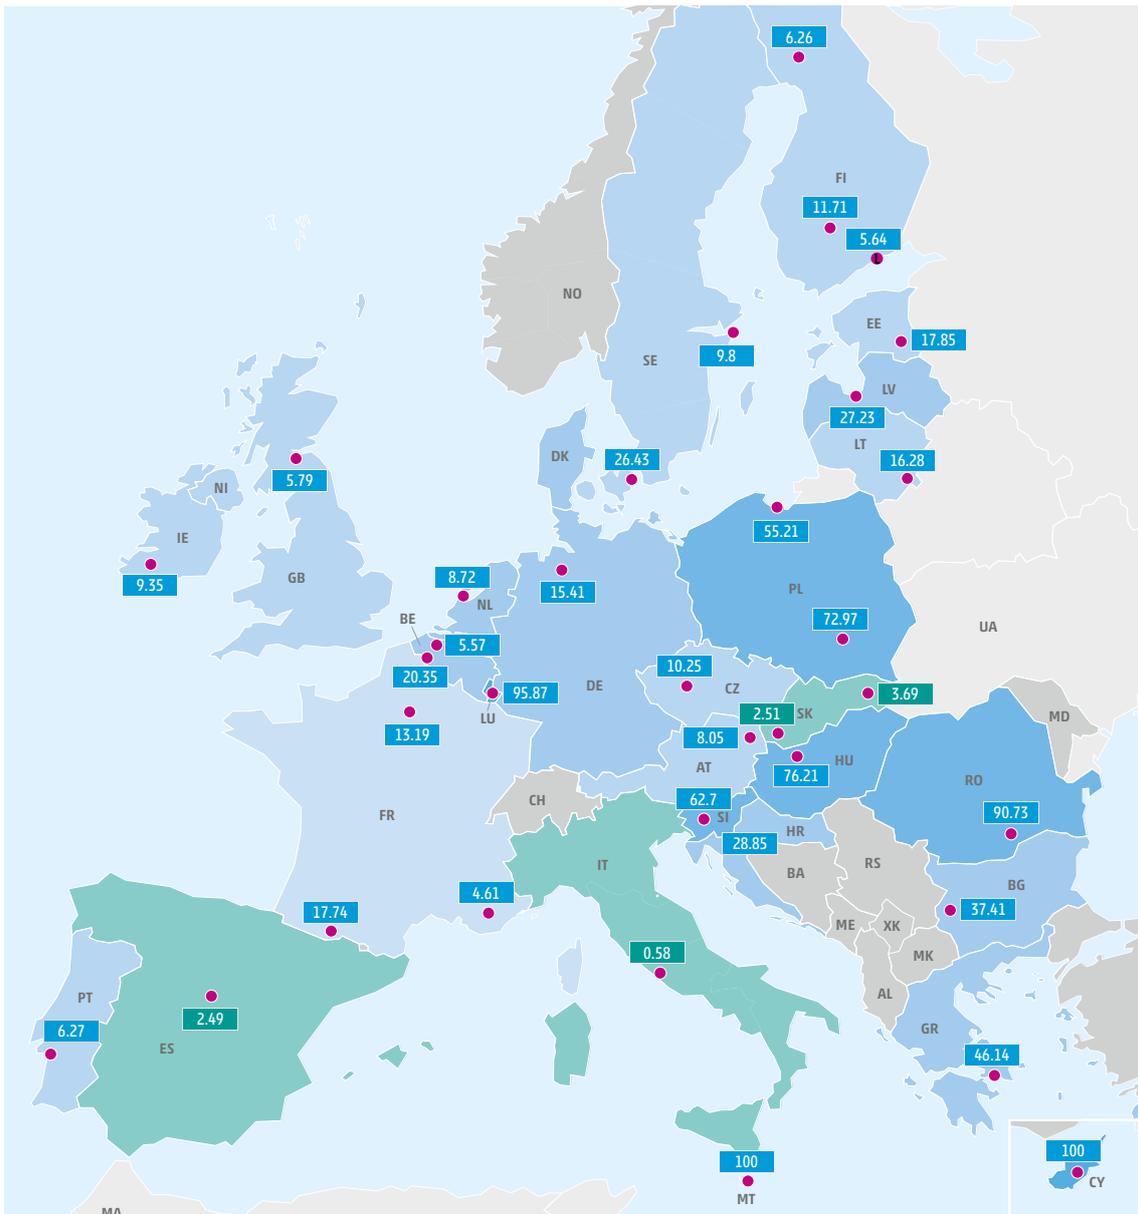

Figure 31: Yearly average hydrogen demand curtailment rate at country or node level in the PCI/PMI hydrogen infrastructure level in 2040 for stressful weather year (unit: %).

Node	Demand curtailment rate (%)	Node	Demand curtailment rate (%)
ATH ₂	8.05	HUH ₂	76.21
BEh ₂	5.57	IEh ₂	9.35
BEH ₂ Mo	20.35	ITh ₂	0.58

FRh ₂ SW	17.74	SKh ₂ W	3.69
GRh ₂	46.14	UKh ₂	5.79
HRh ₂	28.85		

Table 29: Yearly average hydrogen demand curtailment rate at country/sub-zone level in the PCI/PMI hydrogen infrastructure level in 2040 for stressful weather year (unit: %).

Countries are grouped into five categories based on their average yearly hydrogen demand curtailment rates:

- 1. Rates below 3 %:** Italy, Spain, Slovakia-East region.
- 2. Rates between 3 % and 20 %:** Belgium, Slovakia-West region, Portugal, Sweden, Ireland, Finland, Estonia, the Netherlands, Austria, Czechia, Lithuania, France, France-North region, France-South region, France-Southwest region, Latvia.
- 3. Rates above 20 % and below 50 %:** Belgium-Mons region, Greece, Denmark, Croatia, Germany, Bulgaria.
- 4. Rates above 50 % and below 100 %:** Slovenia, Romania, Luxembourg, Poland-North region, Poland-South region, Hungary.
- 5. Full curtailment of 100 %:** Cyprus, Malta.

Countries and regions with hydrogen curtailment rates below 3 % in 2040 include Italy, Spain, Slovakia East Region. These countries and regions demonstrate remarkable resilience even under stressful weather conditions. For instance, Spain achieves a low curtailment rate of 2.5 %, owing to its robust hydrogen production and storage system. The Slovakia-East region, at 2.5 %, benefits from

enhanced import capabilities from Ukraine that effectively mitigates supply disruptions during adverse weather.

Group 2 includes the Belgium, Slovakia-West region, Portugal, Sweden, Ireland, Finland, Estonia, the Netherlands, Austria, Czechia, Lithuania, France, France-North region, France-South region, France-Southwest region, Latvia. Their curtailment rates exceed the 3 % threshold but remain below 20 %. Slovakia-West, for example, reports a curtailment rate of 3.7 %, reflecting its reliance on imports to bridge domestic production gaps. Similarly, Finland's regions show slight variations, driven by reduced wind and hydropower outputs during the stressful weather year.

Belgium-Mons region, Greece, Denmark, Croatia, Germany, Bulgaria are part of group 3, exhibiting more significant curtailment challenges. Greece, with a curtailment rate of 46.1 %, struggles due to its limited domestic production and dependency on solar energy, which is significantly affected by the stressful weather year. The Belgium-Mons region, at 20.4 %, reflects the localised nature of its hydrogen supply challenges, as this region operates as a distinct hydrogen cluster. Germany, with a hydrogen demand curtailment rate of 21.4 %, faces increasing hydrogen demand in its industrial and

transportation sectors, exacerbated by reduced renewable output in a stressful weather year.

Countries in group 4 experience severe curtailment challenges under adverse weather conditions. Slovenia's hydrogen demand curtailment rate improves slightly from 76.6 % in 2030 to 62.7 % in 2040 but remains high due to inadequate infrastructure and limited renewable energy supply. Poland shows a clear regional disparity, with the Southern region exhibiting a higher curtailment rate (73 %) compared to the Northern region (55.2 %).

Hungary, at 76.2 %, faces significant constraints driven by its growing hydrogen demand and insufficient cross-border capacity to meet needs during stressful weather periods. Luxembourg's hydrogen demand curtailment rate of 95.9 % underscores its continued need for connection and lack of domestic production, which are further impacted during adverse weather.

Malta and Cyprus experience full curtailment of 100 % in 2040, as these countries remain entirely isolated and have no hydrogen production assets.

Threshold 2: hydrogen demand curtailment rate of more than 5 % for at least one month per year

All the countries and regions that exceed threshold 1 also exceeded threshold 2.

7.1.2 ADVANCED HYDROGEN INFRASTRUCTURE LEVEL

High-level results for reference weather year

The overall yearly supply-demand balance for the advanced hydrogen infrastructure level in 2040 is presented in Table 30. As detailed in Table 30, overall hydrogen demand more than triples compared to the 2030 hydrogen demand level, leading to a yearly hydrogen demand of 1936 TWh/y in Europe.

Whereas the overall foreseen hydrogen demand does not vary between the analysed infrastructure levels, there are significant differences between them in terms of i) hydrogen demand curtailment and ii) availability of the different supplies.

The advanced infrastructure level shows a lower overall hydrogen demand curtailment rate in Europe. The reduction in the demand curtailment in this infrastructure level is related to the higher availability of hydrogen shipped imports and the maximization of the use of pipeline imports, more specifically Norwegian, North African and Ukrainian imports. The maximization of imports is possible thanks to the consideration of non-PCI/PMI advanced infrastructure that enables transport to countries that were isolated in the PCI/PMI infrastructure level, through the SK/HU/RO hydrogen corridor, as well as, the maximization of national production (both from electrolytic and natural-gas based) through a higher utilization of PCI/PMI infrastructure.

Despite i) the infrastructure development foreseen in the Advanced hydrogen infrastructure level for 2040 (see section 3.2), ii) the increase of extra-EU supply potentials via terminals and pipelines, and iii) the significant increase of electrolytic hydrogen production (by approximately 250 % compared to 2030), this is not sufficient to satisfy the hydrogen demand in many European countries and therefore, overall hydrogen demand curtailment rises compared to the 2030 values leading to an average hydrogen curtailment of 12 % in Europe. This is lower than the 15 % average hydrogen demand curtailment in Europe in the PCI/PMI hydrogen infrastructure level. This reduction is related to the higher availability of hydrogen terminals and the maximization of the use of pipeline imports from Norway, North Africa and Ukraine. The maximization of imports is possible thanks to the consideration of non-PCI/PMI advanced infrastructure that enables transport to countries that were isolated in the PCI/PMI hydrogen infrastructure level. This relates to the transit route through Slovakia, Hungary and Romania as well as the maximisation of national hydrogen production enabled by increased capacities.

Yearly hydrogen supply-demand balance	Advanced IL 2030	Advanced IL 2040
H ₂ produced via electrolysis	304	1,080
H ₂ produced using natural gas	224	168
H ₂ shipped imports	24	110
H ₂ pipeline imports	42	335
Curtailed H ₂ demand	27	237
H ₂ demand for power production	2	77
Total H₂ demand	620	1,929

Table 30: Supply and demand balance in the Advanced hydrogen infrastructure level in 2030 and 2040 for reference weather year (unit: TWh/y).

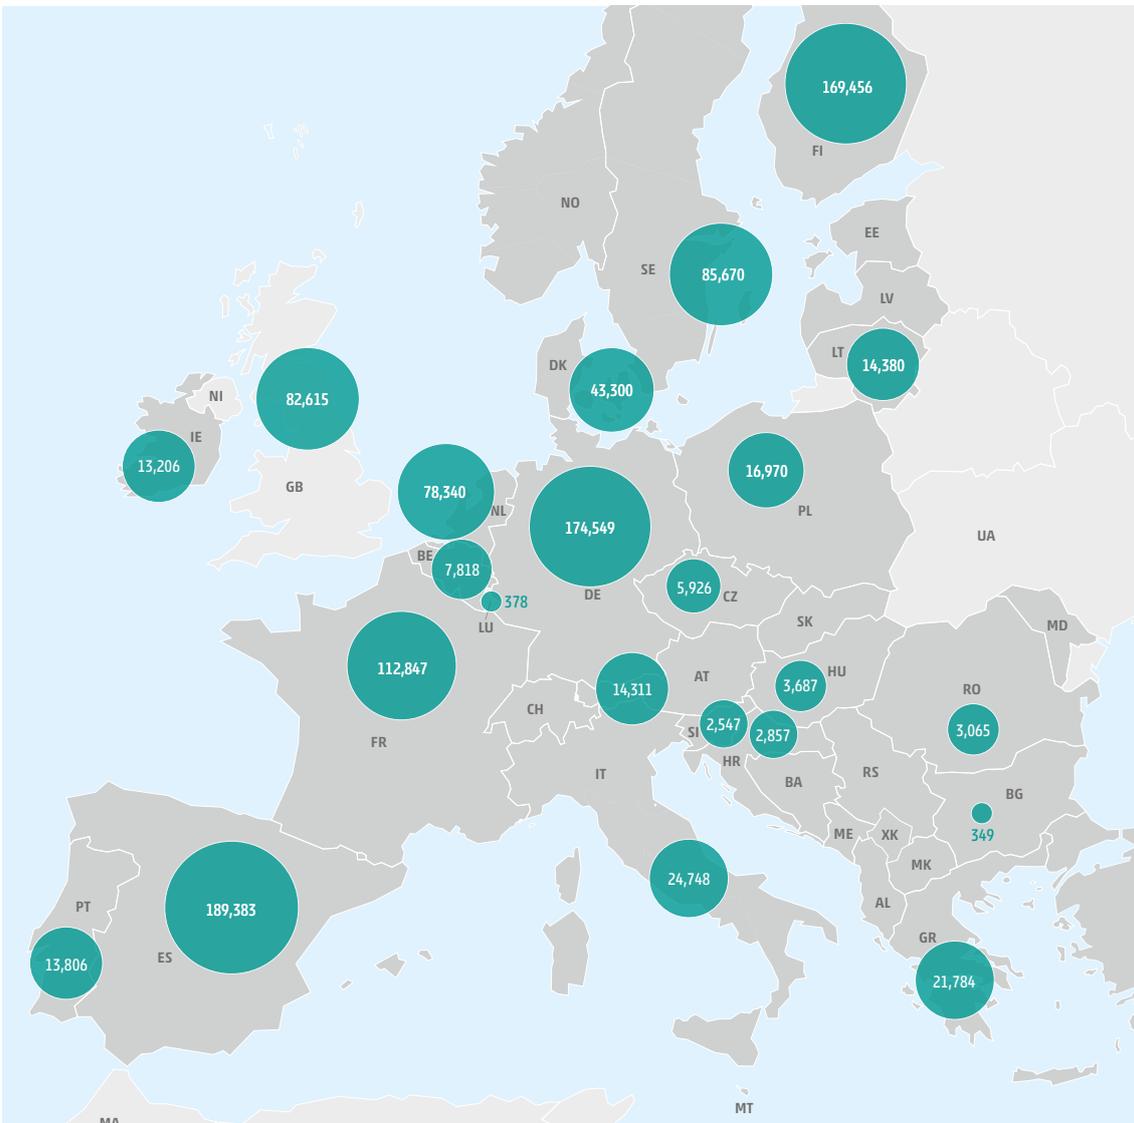

Figure 32: Distribution of electrolytic hydrogen production in the Advanced hydrogen infrastructure level in 2040 for reference weather year (unit: GWh/y).

Figure 32 shows the electrolytic hydrogen production in the different European countries for the Advanced hydrogen infrastructure level in the 2040 assessment. The European electrolytic production significantly increased compared to 2030 in most European countries. The electrolytic production slightly varies country to country in comparison to the PCI/PMI hydrogen infrastructure level, being slightly higher for the Advanced hydrogen

infrastructure level in 2040. However, the overall distribution across Europe is rather similar.

Figure 33 shows the distribution of hydrogen production from natural gas in 2040. There is a reduction in hydrogen production from natural gas compared to 2030. The reasons for this are explained in section 7.1.1.

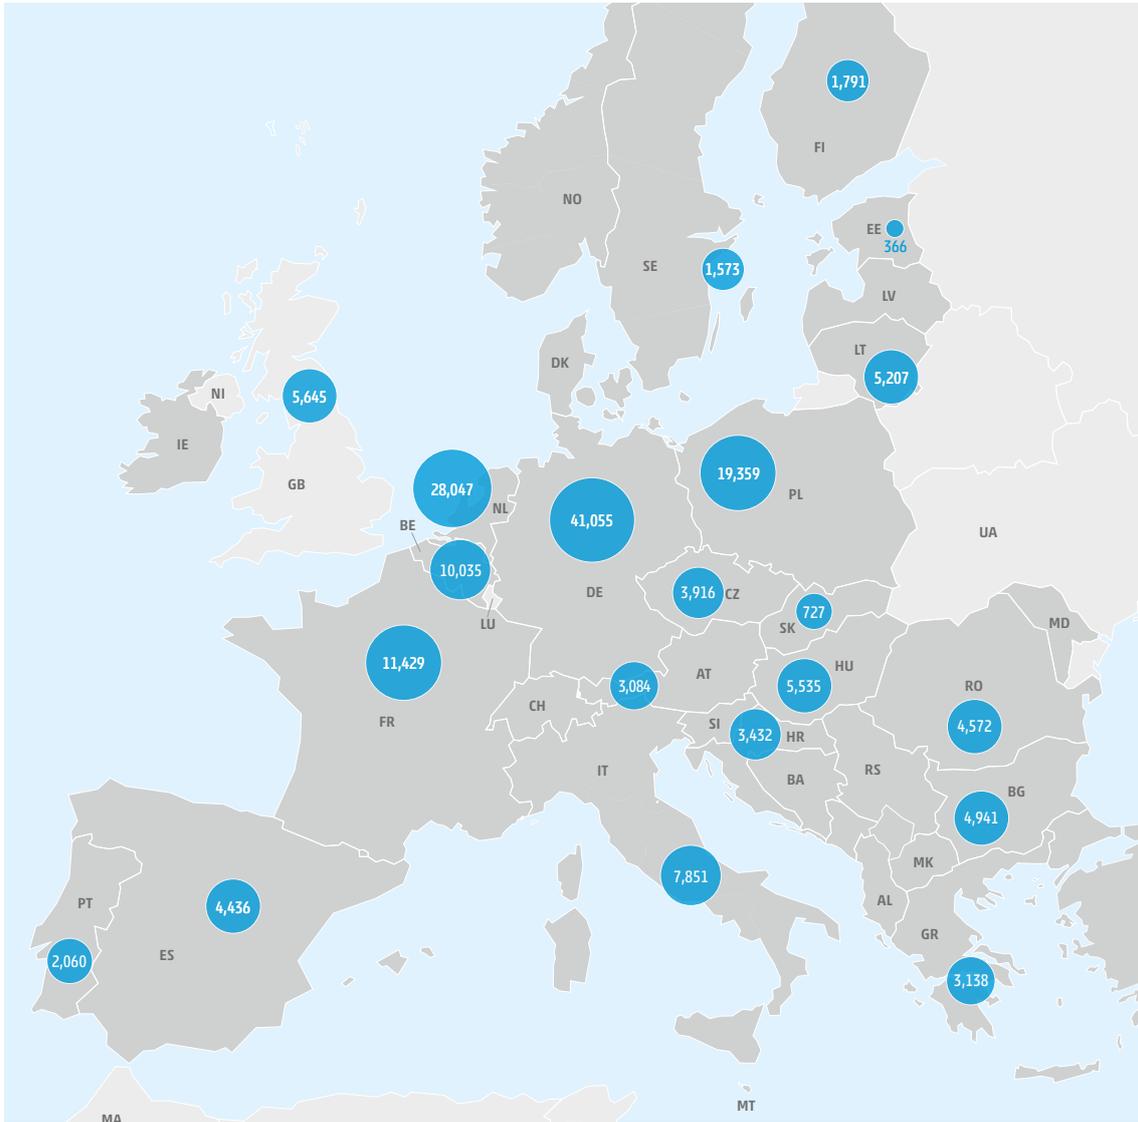

Figure 33: Distribution of hydrogen production from natural gas in the Advanced hydrogen infrastructure level in 2040 for reference weather year (unit: GWh/y).

Country	H ₂ Production via electrolysis	H ₂ Production using natural gas	H ₂ extra-EU imports by pipeline & ship	H ₂ demand

Table 31: Distribution of hydrogen production, imported hydrogen and demand per country in the advanced hydrogen infrastructure level in 2040 for reference weather year (unit: GWh/y).

Considering the supply and demand distribution presented in Table 31, the intra-EU transport corridors that already emerged in the 2030 assessment of the Advanced hydrogen infrastructure level as well as new supply corridors are even more needed in the 2040 assessment due to the increase of hydrogen demand between 2030 and 2040. These corridors are the Iberian and the Baltic corridors as well as the North African corridor with the main European hydrogen hub in Germany.

In addition, as presented in Figure 34, other intra-EU transport corridors emerge, mainly driven by the availability of extra-EU supplies in the 2040 assessment. Namely, the new corridors identified for 2040 are:

- ▲ Norwegian corridor, transporting Norwegian supplies to Germany.
- ▲ Ukrainian corridor, transporting Ukrainian supplies to Slovakia and Czechia and other countries.

In the 2040 Advanced hydrogen infrastructure level assessment for the reference weather year, countries can be grouped in four different categories according to their supply-demand balance on a yearly basis:

- 1. Countries which export more than they import:** Sweden, Finland, Denmark, the Netherlands, Spain, Portugal, Greece.
- 2. Countries that import more than they export:** Belgium, Poland, Czechia, Bulgaria and Romania.
- 3. Transit countries that import more than they consume:** Italy, Austria, Germany, Slovakia, Estonia, Latvia, Lithuania and France.

4. Isolated countries: the United Kingdom, Ireland, Luxembourg, Slovenia, Croatia, Malta, Cyprus, and the cluster Bulgaria-Greece.

With the exception of Hungary and Romania, that are integrated in the European hydrogen network through the Slovakia-Hungary-Romania hydrogen route, among the previously interconnected countries, the exporting/importing and transit roles did not change significantly in comparison to the PCI/PMI hydrogen infrastructure level assessment for 2040 (see Figure 28).

High-level results for stressful weather year

The overall yearly supply-demand balance for the Advanced hydrogen infrastructure level in 2040 for the stressful weather year is presented in Table 32. Electrolytic hydrogen production is the main source of hydrogen in Europe but it is reduced in comparison with the reference weather year. To compensate the reduction of electrolytic hydrogen production, hydrogen import sources, mainly via ship, increase in comparison with the reference weather year. The imports via terminals increase by 10 %. Pipeline imports however hardly increase as the effective import potential is limited by the import capacities

of import pipelines (see Table 5) and by EU-internal bottlenecks (see section 7.2.1), there already were high utilisations in the reference weather year, and there is missing hydrogen storage infrastructure.

The consideration of a stressful weather year leads to an approximate rate of 15 % of hydrogen demand curtailment at European level. This is an increase compared to the 12 % for the reference weather year with the Advanced hydrogen infrastructure level and a reduction compared to the 18 % for the stressful weather year with the PCI/PMI hydrogen infrastructure level.

Yearly hydrogen supply-demand balance	Advanced IL 2030	Advanced IL 2040
H₂ produced via electrolysis	265	1,002
H₂ produced using natural gas	241	170
H₂ shipped imports	35	121
H₂ pipeline imports	42	336
Curtailed H₂ demand	38	298
H₂ demand for power production	2	75
Total H₂ demand	620	1,927

Table 32: Supply and demand balance in the advanced infrastructure level in 2030 and 2040 for stressful weather year (unit: TWh/y).

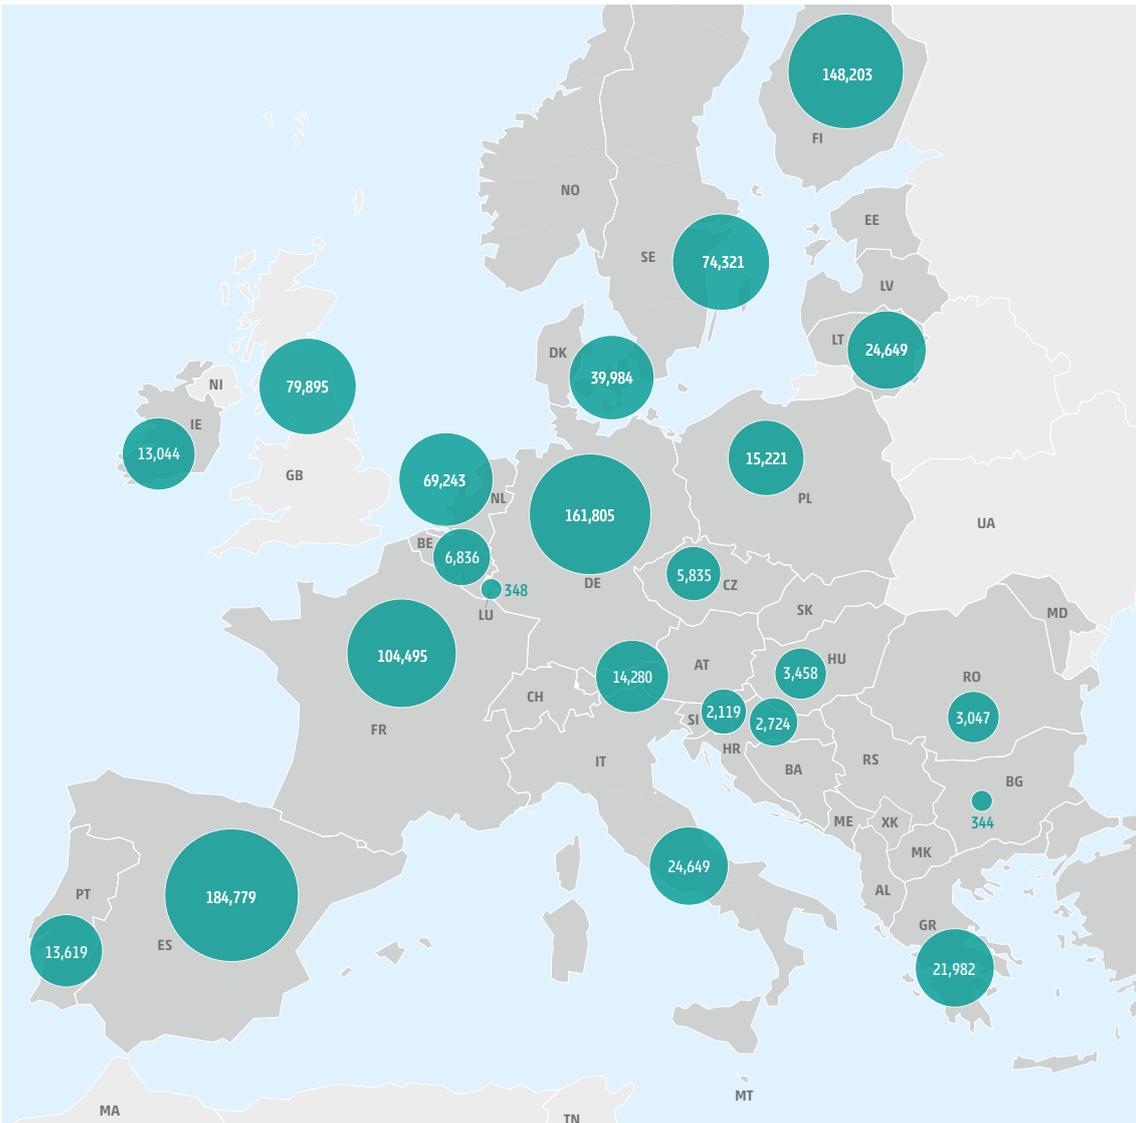

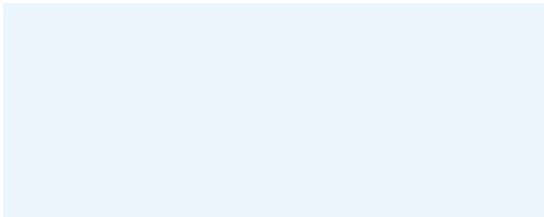

Figure 35: Distribution of electrolytic hydrogen production from natural gas in the Advanced hydrogen infrastructure level in 2040 for stressful weather year (unit: GWh/y).

Figure 35 shows the distribution of electrolytic hydrogen production in the different European countries for the Advanced hydrogen infrastructure level in the 2040 assessment under stressful weather conditions. While keeping the same overall distribution as in the reference case, the electrolytic production was reduced all over Europe.

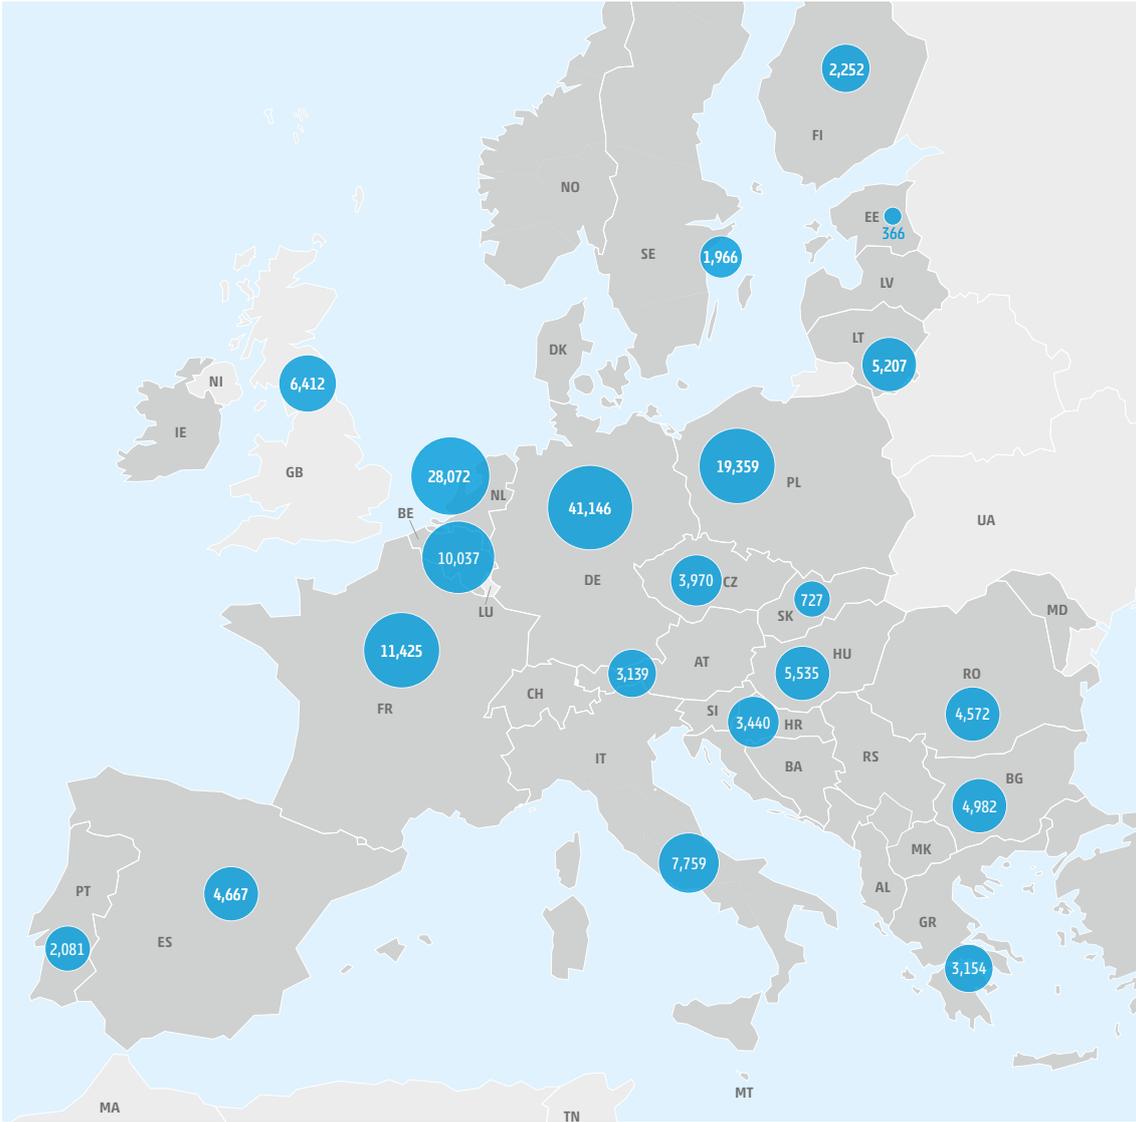

Figure 36: Distribution of hydrogen production from natural gas in the advanced infrastructure level in 2040 for stressful weather year (unit: GWh/y).

Figure 36 shows the distribution of natural-gas based hydrogen production in the different European countries for the Advanced hydrogen infrastructure level in the 2040 assessment under stressful weather conditions. No significant change was observed in comparison to the reference weather year presented in Figure 33.

Table 33: Distribution of hydrogen production, imported hydrogen and demand per country in the Advanced hydrogen infrastructure level in 2040 for stressful weather year (unit: GWh/y).

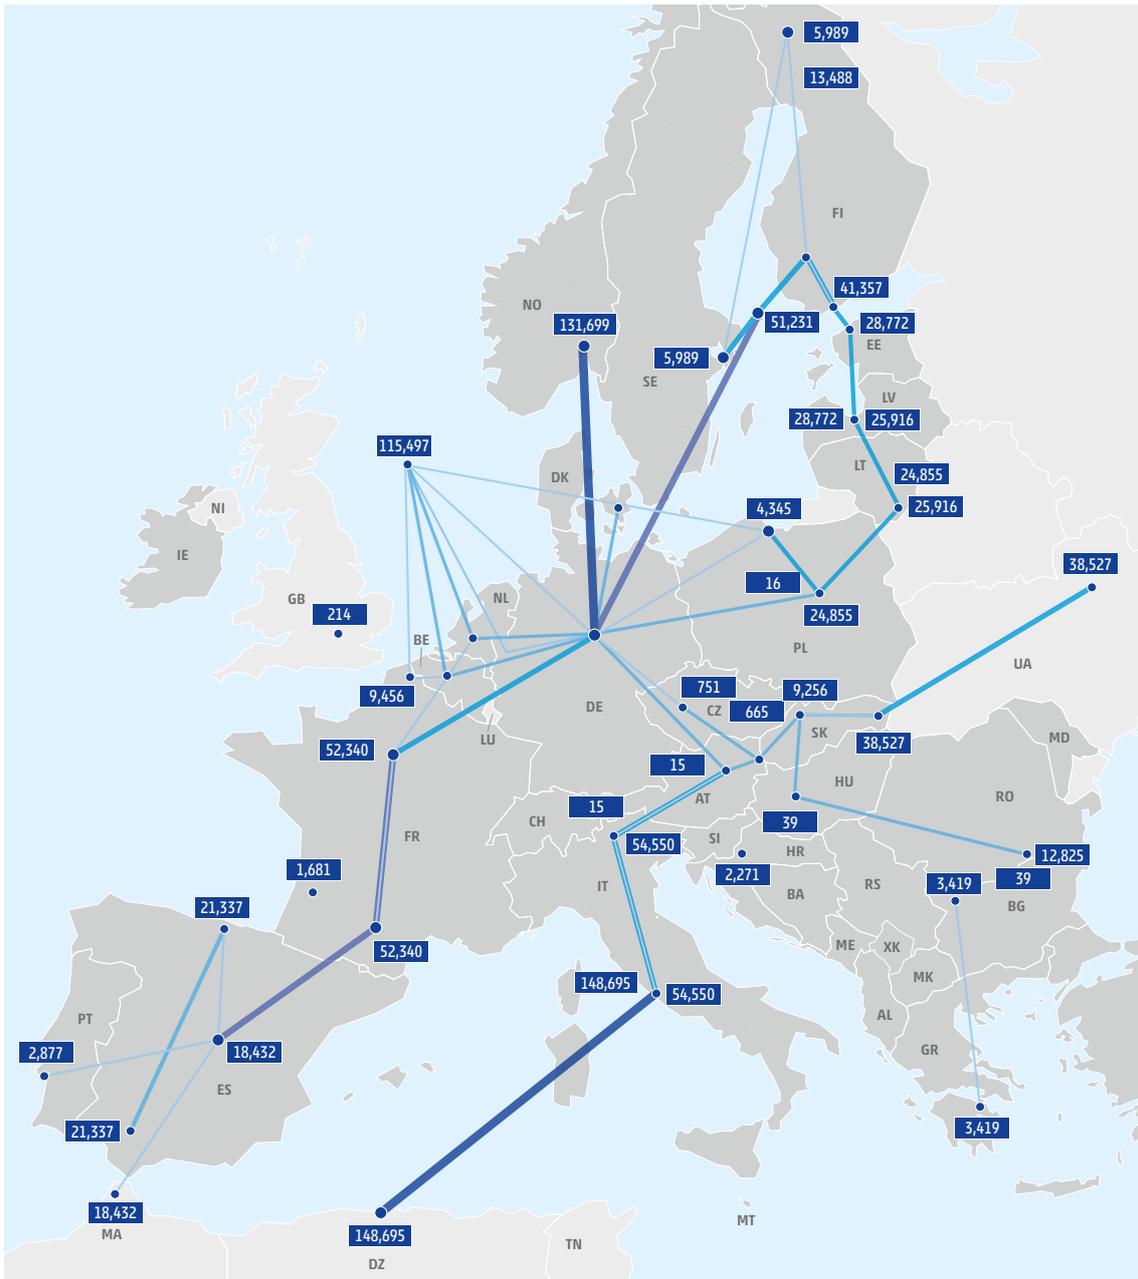

Figure 37: Grid flows* in the Advanced hydrogen infrastructure level in 2040 for stressful weather year (unit: GWh/y).

* Grid flows refer to simulations results and do not intend to represent how the European infrastructure is expected to evolve in the simulated years, being just outcomes of a modelling tool. The values are provided as a table in Annex II and as monthly values in Annex III).

When comparing Figure 34 with Figure 37, most European countries show the same behaviour in terms of being a net exporter, a net importer or a transit country for the stressful as for the reference weather year. As expected under stressful climatic conditions, corridors based mainly on electrolytic production will see their exporting role slightly reduced due to the lower availability of RES (i.e., Iberian and Nordic corridors).

Consequently, also the transit through countries along these routes is reduced (e.g., transit through Baltic countries). On the contrary, countries with access to import terminals will increase imports via ship for own consumption and transit. In addition, imports via pipeline from Ukrainian and North African corridors slightly increase their imports up to the maximum capability, determined by supply potentials and infrastructure bottlenecks.

7.1.2.1 IGI INDICATOR 1: HYDROGEN MARKET CLEARING PRICE SPREADS FOR REFERENCE WEATHER YEAR

Overview: Hydrogen market clearing prices per country

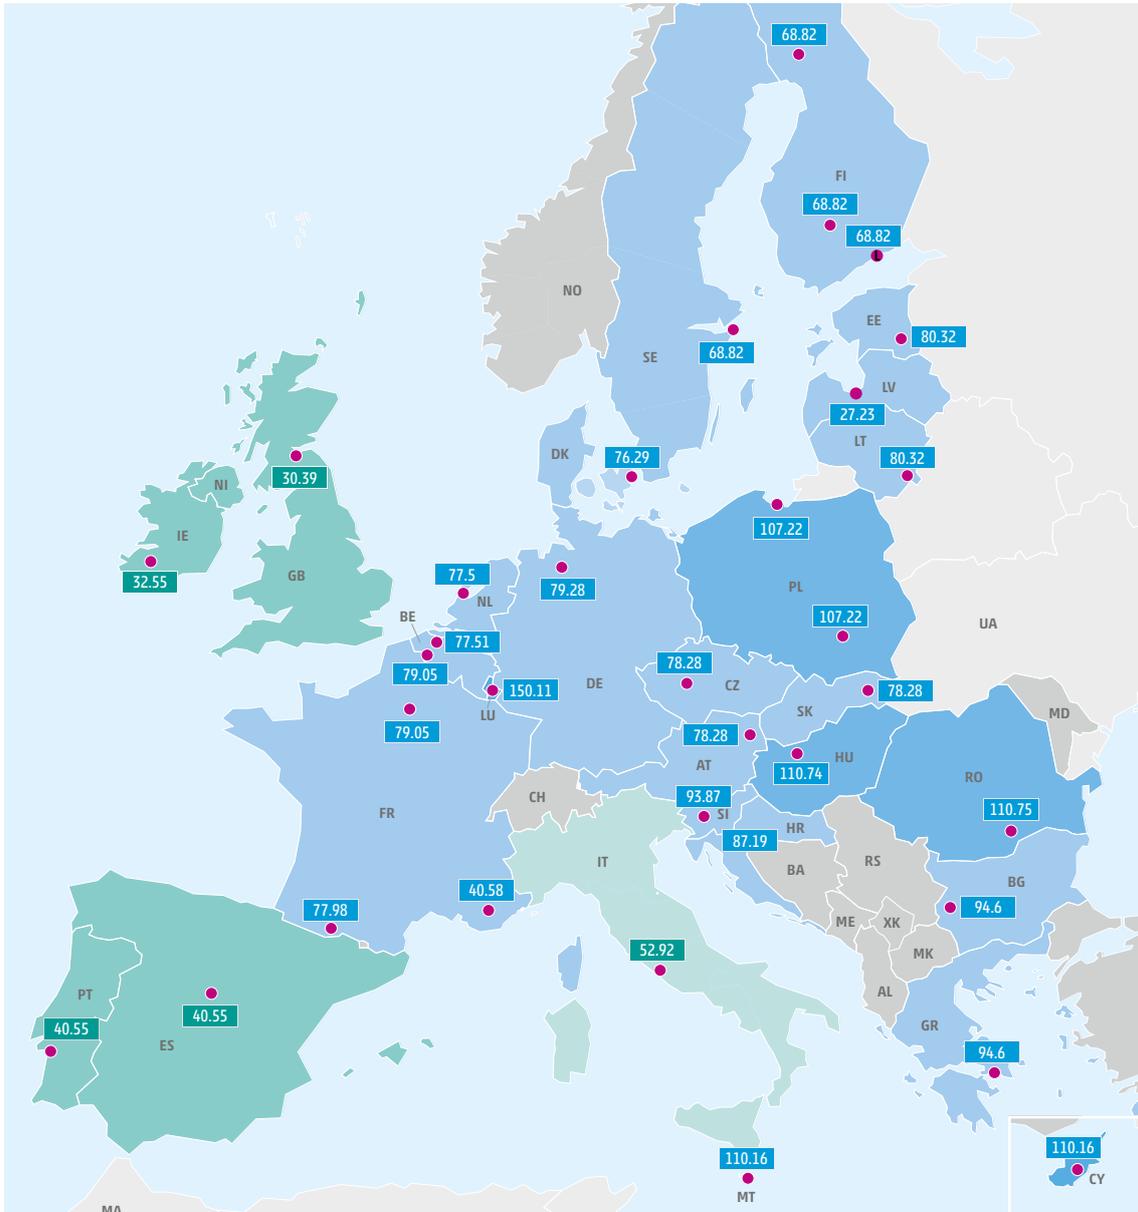

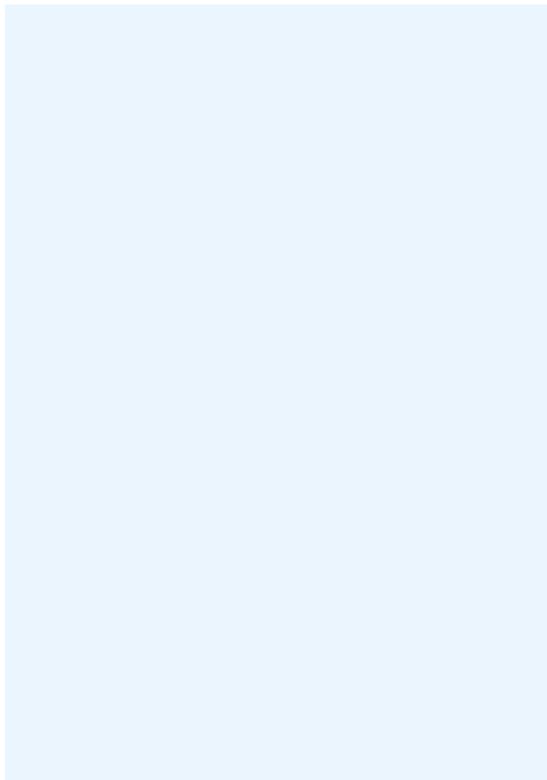

Figure 38: Average of the hourly hydrogen market clearing prices per country in the Advanced hydrogen infrastructure level in 2040 (unit: €/MWh).

The increase of hydrogen demand considered in the 2040 assessment leads to a general increase of average hydrogen market clearing prices in Europe when compared to the 2030 assessment, as represented in Figure 38. The fundamental reasons are explained in section 7.1.1.1 The Advanced hydrogen infrastructure level considers a significant increase of import terminal capacities (see Table 6 in section 3.2), increasing the overall availability of shipped hydrogen imports.

Despite having lower overall hydrogen demand curtailment in the Advanced hydrogen infrastructure level, hydrogen market clearing prices in most European countries are higher than in the PCI/PMI hydrogen infrastructure level for 2040 and lower in some countries like Poland. This relates to the improved connectivity that enables more countries to compete for the hydrogen supply options, maximising the overall socio-economic welfare that includes (among others) the surplus of all the hydrogen consumers as well as the surplus of the hydrogen producers.

The price formation in the DHEM is based on the merit order of hydrogen production (see section 4.1). Several price groups stand out, while a significant correlation is understood here as a correlation above 0.7:

- 1. Portugal, Spain, France-South region:** Portugal and Spain are producers and net exporters of electrolytic hydrogen from RES to other countries. While the France-South region is sufficiently connected to the Iberian peninsula, price spreads appear with other groups of (regions of) countries due to an internal bottleneck in France. The prices in this group show no significant correlation with the prices in other groups.
- 2. France-Southwest region:** The prices in this group show no significant correlation with the prices in other groups. The group exists due to bottlenecks within France.
- 3. France-North region:** The prices in this group show significant correlations with prices in groups 4, 5, 6, 7, 11. The group exists due to bottlenecks within France.
- 4. France, Belgium-Mons region:** The prices in this group show significant correlations with prices in groups 3, 5, 6, 7, 10, 11. The group exists due to bottlenecks within France and Belgium.
- 5. Belgium, the Netherlands:** The prices in this group show significant correlations with prices in groups 3, 4, 6, 7, 10, 11. The group exists due to bottlenecks with France and Germany.
- 6. Denmark:** The prices in this group show significant correlations with prices in groups 4, 5, 7, 10, 11. The group exists due to a bottleneck from Denmark to Germany.
- 7. Germany, Czechia, Austria, Slovakia-East region, Slovakia-West region:** The group grew by Slovakia-East and Slovakia-West regions in comparison with the PCI/PMI hydrogen infrastructure level. The prices in this group show significant correlations with prices in groups 3, 4, 5, 6, 10, 11. The group exists due to bottlenecks from France to Germany, from Belgium to Germany, from Denmark to Germany, from Italy to Austria, from Slovakia to Hungary, from Germany to Finland and Sweden, and from Germany to Poland.
- 8. Italy:** While being connected to Austria, the bottleneck between Italy and Austria is so dominant that Italy has no correlation with the prices in other groups.
- 9. Poland-North region, Poland-South region:** This group grew by the Poland-South region in comparison with the PCI/PMI hydrogen infrastructure level.
- 10. Sweden, Finland:** The prices in this group show significant correlations with prices in groups 3, 4, 5, 6, 7, 11. The group exists due to a bottleneck between Sweden/Finland and Germany and a bottleneck between Finland and Estonia.
- 11. Estonia, Latvia, Lithuania:** The prices in this group show significant correlations with prices in groups 3, 4, 5, 6, 7, 10. The group exists due to a bottleneck between Finland and Estonia as well as bottlenecks from Lithuania to Poland and within Poland.
- 12. Ireland, the United Kingdom:** Isolated countries without significant price correlations but with average prices below 100 €/MWh.
- 13. Greece, Bulgaria:** Countries showing significant price correlation, jointly isolated from the other European countries.
- 14. Croatia (only connected to Bosnia), Slovenia, Luxembourg, Cyprus, Malta:** Isolated countries without significant price correlations (except for Croatia and Slovenia due to a similar national hydrogen production constellation) and with average prices above 100 €/MWh.

The IGI indicator 1 in the 2040 assessment of the Advanced hydrogen infrastructure level reveals the same borders that were identified in the PCI/PMI hydrogen infrastructure level assessment for 2040.

Border	Threshold 1: Absolute average hourly hydrogen market clearing price spread above 4 €/MWh (number of days)	Threshold 2: More than 40 days with hydrogen market clearing price spread above 20 €/MWh (number of days)

Table 34: List of borders in the advanced hydrogen infrastructure level that exceed (at least one of) the thresholds defined for IGI indicator 1 in 2040 (unit: days).

7.1.2.2 IGI INDICATOR 2.1: HYDROGEN DEMAND CURTAILMENT FOR REFERENCE WEATHER YEAR

As explained in section 4.2, this IGI indicator assesses infrastructure gaps by quantifying hydrogen demand curtailments at individual nodes during the reference weather year, assuming no disruptions of infrastructures or of supply sources. It involves a multi-step simulation process integrating DHEM and DGM¹⁶ outputs to evaluate the combined curtailments across nodes. The assessment is performed for the advanced hydrogen infrastructure level in 2040, showing the effects of matured infrastructure in 2040.

Figure 36 and Table 35 show yearly average curtailment rates of hydrogen demand in the Zone 2 nodes of different European countries. For countries where the hydrogen market is divided into several sub-zones (i.e., nodes), the curtailment rate in the different sub-zones is presented. The yearly average hydrogen curtailment rates are thereby colour-coded in the map to indicate levels relative to the set threshold: blue signifies curtailment above the threshold, while green represents rates that are not above it.

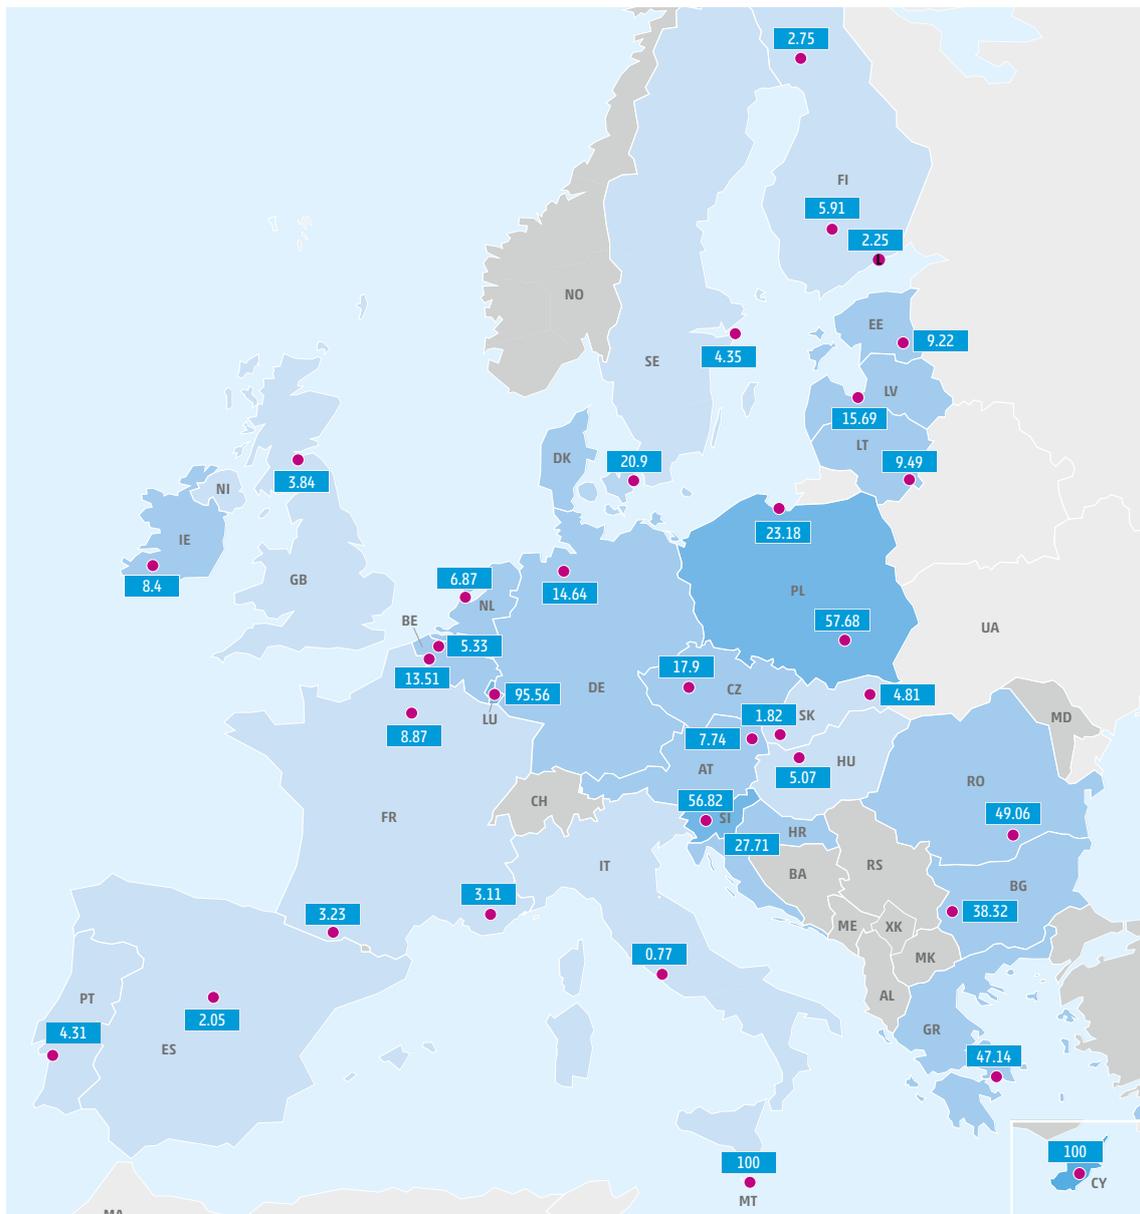

Figure 39: Yearly average hydrogen demand curtailment rate at country or node level in the advanced hydrogen infrastructure level in 2040 for reference year (unit: %).

¹⁶ This draft TYNDP 2024 IGI report only includes the simulation results of the DHEM.

Country/Region	Demand Curtailment (%)	Threshold passed	Country/Region	Demand Curtailment (%)	Threshold passed

HRH ₂	27.71	YES			

Table 35: Yearly average hydrogen demand curtailment rate at country/sub-zone level in the Advanced hydrogen infrastructure level in 2040 for reference weather year and check of the threshold of IGI indicator 2.1 (unit: %).

All European countries and regions overshoot the threshold of 0 % for IGI indicator 2.1 under the Advanced hydrogen infrastructure level in 2040. However, differences in the hydrogen curtailment rates between nodes are related to the level of infrastructure development and supply availability. In comparison with IGI indicator 1, this IGI indicator focusses on the availability of supplies.

As detailed in Figure 39, (regions of) countries can be aggregated in different groups according to their average yearly hydrogen demand curtailment rates:

- 1. Rates below 5 %:** Spain, Finland-North region, Finland-South region, France-South region, France-Southwest region, Italy, Portugal, Sweden, Slovakia-East, Slovakia-West, the United Kingdom.
- 2. Rates between 5 % and 20 %:** Austria, Belgium, Belgium-Mons region, Czechia, Germany, Estonia, Finland, France, Hungary, Ireland, Lithuania, Latvia, the Netherlands.
- 3. Rates between 20 % and 50 %:** Bulgaria, Denmark, Greece, Croatia, Poland-North, Romania.

4. Rates between 50 % and 100 %: Slovenia, Luxembourg, Poland-South.

5. Full curtailment of 100 %: Cyprus, Malta.

Without the infrastructure already considered in the hydrogen infrastructure level, the overall hydrogen demand curtailment would be higher.

While hydrogen demand curtailment rates decrease in newly connected countries and regions and the overall hydrogen demand curtailment in Europe decreases compared to the PCI/PMI hydrogen infrastructure level, the curtailment rates in several countries and regions increase slightly, as other, newly connected countries and regions are supplied instead.

Considering group 1, in comparison with the PCI/PMI hydrogen infrastructure level, improved infrastructure could especially enhance the curtailment situation of the France-Southwest region (11.5 % to 3 %).

Within group 2, especially Hungary could benefit from its new interconnection in the Advanced hydrogen infrastructure level (75 % to 5 %).

Countries and regions of group 3 see the most significant reduction in the Poland-North region (50 % to 23 %) due to additional capacities in the Advanced hydrogen infrastructure level as well as in Romania (90 % to 49 %) due to its new inter-connection with Hungary. Here, Hungary is acting as a transit country for hydrogen it receives from Slovakia.

In group 4, advanced infrastructure projects mitigate curtailment in Poland-South.

Malta and Cyprus, representing group 5, remain fully curtailed due to their geographic isolation within the European hydrogen market and have no hydrogen production assets.

In the Poland-North Region, France and Czechia, on top of the curtailments observed in Zone 2 nodes as described in the paragraphs above, hydrogen demand curtailments can be observed in Zone 1 that increase during the winter months.

7.1.2.3 IGI INDICATOR 2.2: HYDROGEN DEMAND CURTAILMENT FOR STRESSFUL WEATHER YEAR

Threshold 1: Average yearly hydrogen demand curtailment rate above 3 %

The 2.2 IGI indicator shows the yearly average hydrogen demand curtailment rates in the Zone 2 nodes of various European countries for 2040, simulated under a stressful weather year. This weather scenario assumes adverse conditions, such as reduced wind and solar energy availability, which directly impacts hydrogen production. For countries with

hydrogen markets divided into multiple sub-zones (i.e., nodes), curtailment rates are depicted individually for each sub-zone on the map. The yearly average hydrogen curtailment rates are thereby colour-coded to indicate levels relative to the set threshold 1: blue signifies curtailment above the threshold, while green represents rates that are not.

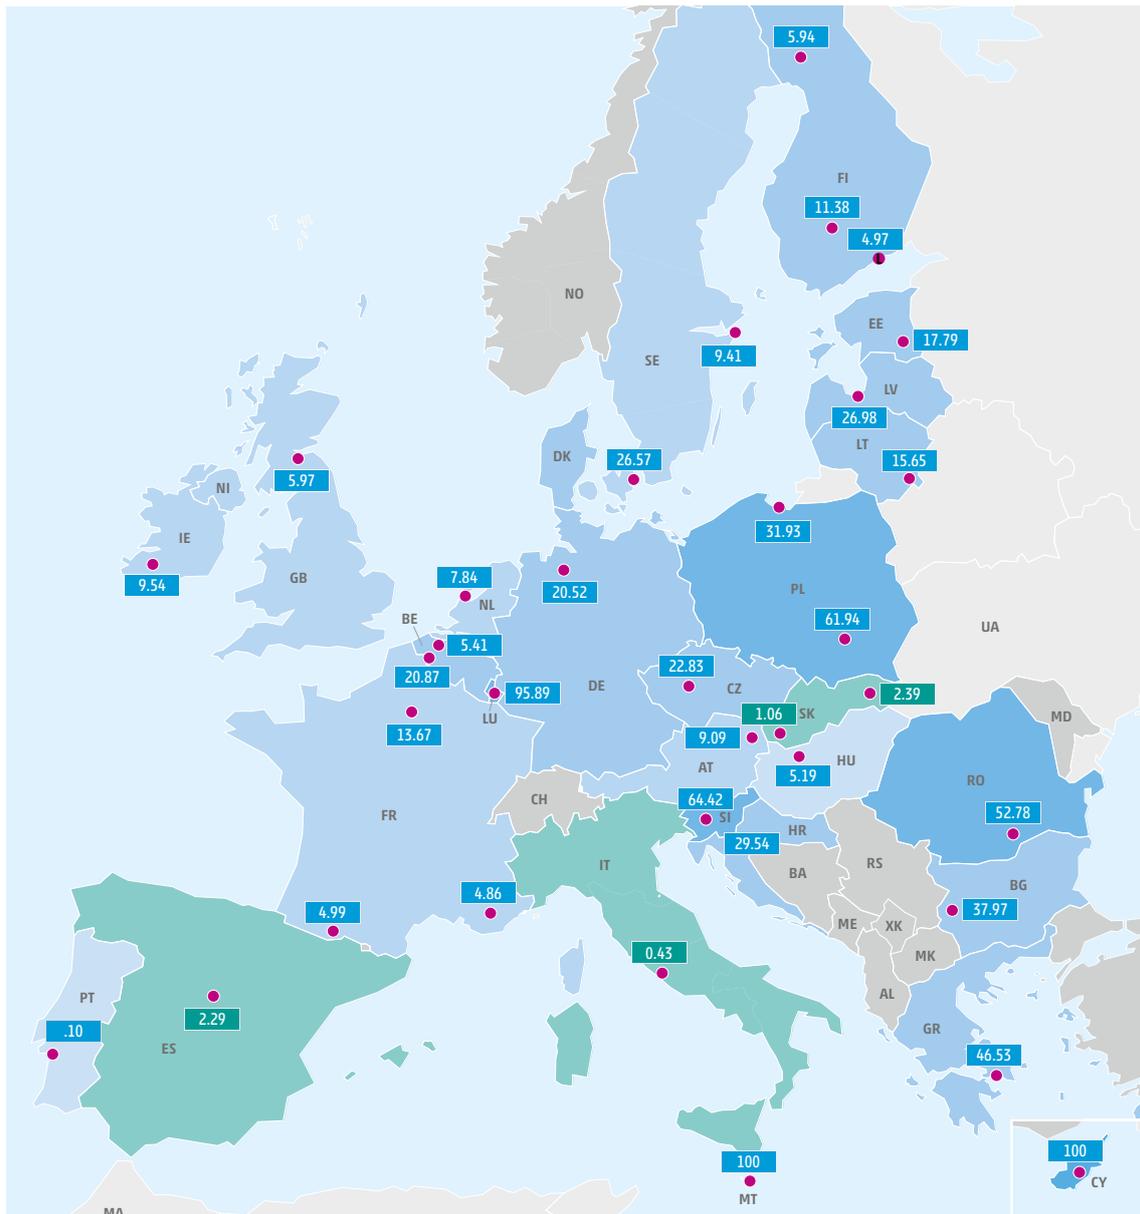

Figure 40: Yearly average hydrogen demand curtailment rate at country or node level in the Advanced hydrogen infrastructure level in 2040 for stressful weather year (unit: %).

Country node	Demand Curtailment (%)	Country node	Demand Curtailment (%)
ATH ₂	9.09	HUH ₂	5.19
BEH ₂	5.41	IEH ₂	9.54
BEH ₂ Mo	20.87	ITH ₂	0.43
BGH ₂	37.97	LTH ₂	15.65
CYh ₂	100.00	LUh ₂	95.89
CZh ₂	22.83	LVh ₂	26.98
DEh ₂	20.17	MTh ₂	100.00
DKh ₂	26.57	NLh ₂	7.84
EEh ₂	17.79	PLh ₂ N	31.93
ESh ₂	2.29	PLh ₂ S	61.94
Flh ₂	11.38	PTH ₂	6.10
Flh ₂ N	5.94	ROh ₂	52.78
Flh ₂ S	4.97	SEh ₂	9.41
FRh ₂	13.67	Slh ₂	64.42
FRh ₂ S	4.86	SKh ₂ E	1.06
FRh ₂ SW	4.99	SKh ₂ W	2.39
GRh ₂	46.53	UKh ₂	5.97
HRh ₂	29.54		

Table 36: Yearly average hydrogen demand curtailment rate at country/sub-zone level in the advanced infrastructure level in 2040 for stressful weather year and check of threshold 1 of IGI indicator 2.2 (unit: %).

Countries and (regions of countries) can be aggregated in different groups according to their average yearly hydrogen demand curtailment rates:

- 1. Rates below 3 %:** Slovakia-East, Slovakia-West, Spain, Italy.
- 2. Rates between 3 % and 20 %:** Austria, Belgium, Estonia, Finland, Finland-North region, Finland-South region, France, France-South region, France-Southwest region, Hungary, Ireland, Lithuania, the Netherlands, Portugal, Sweden, the United Kingdom.

- 3. Rates between 20 % and 50 %:** Belgium-Mons Region, Bulgaria, Czechia, Germany, Denmark, Greece, Croatia, Latvia, Poland-North region.

- 4. Rates between 50 % and 100 %:** Luxembourg, Poland-South region, Romania, Slovenia.

- 5. Full curtailment of 100 %:** Malta, Cyprus.

Compared with the PCI/PMI hydrogen infrastructure level, group 1 grows by the Slovakia-West region, reducing its hydrogen demand curtailment below the threshold of IGI indicator 2.2.

Threshold 2: hydrogen demand curtailment rate of more than 5 % for at least one month per year

All the countries and regions that exceed threshold 1 also exceeded threshold 2.

7.2 COMPARISON BETWEEN PCI/PMI HYDROGEN INFRASTRUCTURE LEVEL AND ADVANCED HYDROGEN INFRASTRUCTURE LEVEL

7.2.1 MAXIMUM UTILISATION OF INTERCONNECTORS

Table 37 displays the maximum utilisation rates of hydrogen interconnections for both hydrogen infrastructure levels in 2040 for the reference weather year. As stated in section 3, some countries are completely isolated from the hydrogen infrastructure:

- ▲ Countries and regions that are isolated in both hydrogen infrastructure levels: Slovenia, Ireland, the United Kingdom, Cyprus, Malta, France-Southwest region, Poland-South region,

Luxembourg. Bulgaria and Greece are interconnected with each other but isolated from the main backbone.

- ▲ Countries that are only isolated in the PCI/PMI hydrogen infrastructure level: Hungary, Romania. Bosnia and Croatia are interconnected with each other in the Advanced hydrogen infrastructure level but isolated from the main backbone.

Interconnection	Stated direction		Reverse direction		Comments
	PCI/PMI IL	ADV IL	PCI/PMI IL	ADV IL	
ATH ₂ → DEh ₂	100	100	100	100	No bottleneck, as alternative route (e.g., through SK and CZ) still has free capacities.
ATH ₂ → IB-ITh ₂	100	45	100	100	Capacity from IT to AT is a bottleneck.
ATH ₂ → IB-SKh ₂ W	100	100	94	87	
BAh ₂ → HRh ₂		0		0	The low utilisation is caused by low hydrogen supply to these jointly isolated countries, so BA and HR always need hydrogen supply themselves if the other country needs it.
BEh ₂ → DEh ₂	100	100	100	100	
BEh ₂ → FRh ₂	100	100	100	100	Capacity from FR to BE is a bottleneck.
BEh ₂ → FRh ₂ N	0	0	100	100	Capacity from FR-North to BE is a bottleneck.
BEh ₂ → NLh ₂	100	100	100	100	No bottleneck, as alternative route (e.g., through DE) still has free capacities.
BEh ₂ Mo → FRh ₂ Va	0	0	39	36	The flow direction is from FR to BE.
BGh ₂ → GRh ₂	0	0	53	46	The flow direction is from GR to BG.
CZh ₂ → DEh ₂	50	50	49	40	
DEh ₂ → DKh ₂	59	87	100	100	Capacity from DK to DE is a bottleneck.
DEh ₂ → FRh ₂	100	100	100	100	Capacity from FR to DE is a bottleneck.
DEh ₂ → NLh ₂	100	100	92	99.9	
DEh ₂ → PLh ₂ N		100		93	Capacity from DE to PL is a bottleneck.
DEh ₂ → PLh ₂ nc	100	100	100	100	Capacity from DE to PL is a bottleneck.
DEh ₂ ba → DEh ₂		0			
DEh ₂ bp → DEh ₂		100			Allows import through DEbp terminal in ADV IL.
DEh ₂ bp → DEh ₂ ba		0			
EEh ₂ → FIh ₂ S	0	0	100	100	Capacity from FI to EE is a bottleneck (as alternative route via DE is also congested at the same time).

Interconnection	Stated direction		Reverse direction		Comments
	PCI/ PMI IL	ADV IL	PCI/ PMI IL	ADV IL	
EEh ₂ → LVh ₂	96	96	0	0	
ESH ₂ → FRh ₂ S	100	100	80	44	Capacity from FR-South to other nodes in FR is the dominant bottleneck.
ESH ₂ → PTh ₂	61	24	0	0	The flow direction is from ES to PT.

Table 38: Maximum utilisation rates of interconnections in the PCI/PMI hydrogen infrastructure level and in the Advanced hydrogen infrastructure level in 2040 for the stressful weather year (unit: %).

Concerning pipelines connecting offshore electrolysers, the following observations are made:

- ▲ Offshore electrolyser node in the Netherlands: A share of the national electrolyser capacity of the Netherlands is allocated to an offshore node. Because it is connected only by capacity from a less-advanced project (HyONE) which is not taken in account in either of the ENTSOG infrastructure levels in this report, Offshore electrolyser node in the Netherlands: A share of the national electrolyser capacity of the Netherlands is allocated to an offshore node. Because it is connected only by capacity from a less-advanced project (HyONE) which is not taken in account in either of the ENTSOG infrastructure levels in this report, the offshore electrolysers are not used in the simulations. This leads to unused renewable hydrogen production offshore. The order of magnitude of this unused renewable hydrogen production offshore would have led to a maximum utilisation rate of 100 % when this less advanced project would be taken into account.
- ▲ Offshore electrolysis in Germany: The offshore electrolysis in Germany (namely in the Northern Sea) is connected to the mainland through the PCI project AquaDuctus. Therefore, the project capacity foreseen for national production is included in the PCI/PMI hydrogen infrastructure level, as well as in the Advanced hydrogen infrastructure level. Maximum utilisation rate will be calculated in the final IGI report as described in the TYNDP 2024 Annex D2 based on the enabled electrolyser capacity and infrastructure level.

7.2.2 ANALYSIS WITH HYPOTHETICAL INFRASTRUCTURE APPROACH

The main purpose of this section is the investigation of any system limitations due to the potential bottlenecks in the PCI/PMI and Advanced infrastructure levels, without any implications regarding the development of specific projects¹⁷. It has been found already in the previous sections that infrastructure gaps were identified between Advanced infrastructure level and PCI/PMI infrastructure level. The Advanced infrastructure level includes all projects presented in the PCI/PMI infrastructure level, as well as additional projects. To explore different possibilities and limitations, four different hypothetical scenarios were defined:

- ▲ **Unlimited Pipes (UP):** unlimited connections between (transmission) nodes;
- ▲ **Unlimited Pipes + Storages (UPS):** unlimited connections between nodes + unlimited storage withdrawal, injection and working gas volume in existing storage countries;
- ▲ **Unlimited Imports (UI):** unlimited imports capacities for imports defined in each infrastructure level and reference years;
- ▲ **Unlimited Storages (US):** unlimited storage withdrawal, injection and working gas volume in existing storage countries;

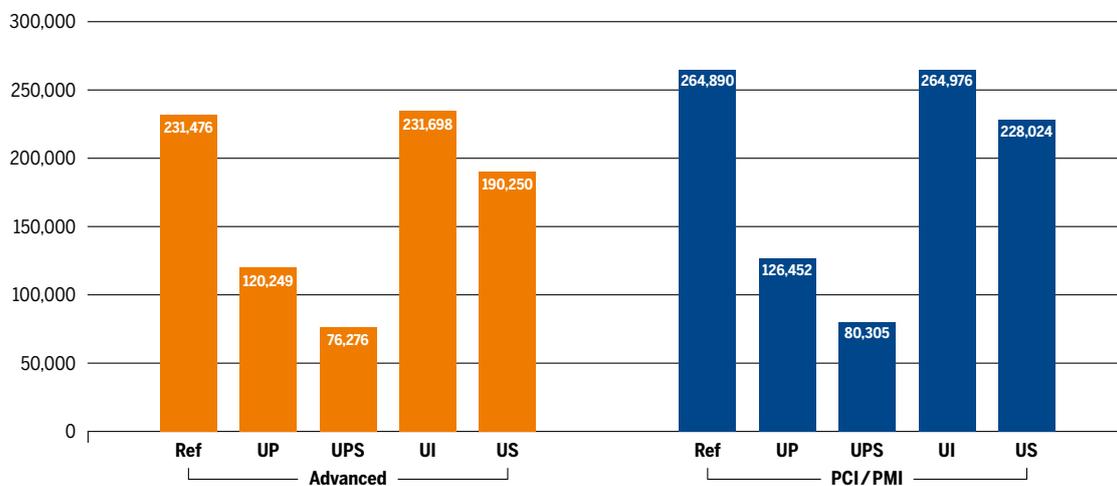

Figure 41: Shortage Advanced level and Shortage PCI/PMI level 2040

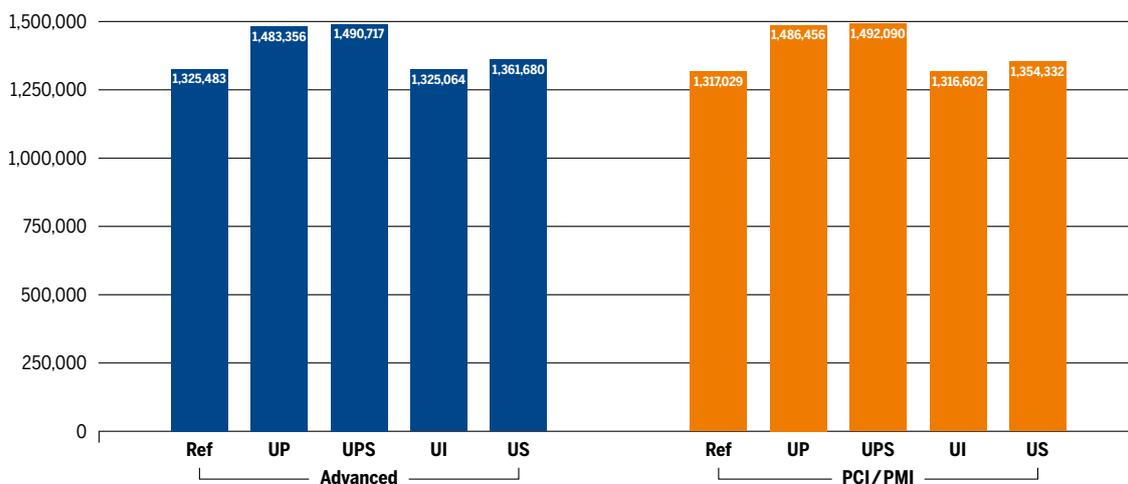

Figure 42: Electrolyser production Advanced level 2040 and PCI level 2040

17 See section 6 of Annex D2 – Hydrogen Infrastructure Gaps Identification Methodology, available on <https://tyndp2024.entsog.eu/downloads/>

Under unlimited pipelines scenario, shortage is mitigated in both cases by more than 50%. Internal bottlenecks are depicting limitations to meet the demand and supply. Moreover, adding more flexibility by utilizing storages is reducing a bit more shortage. Thus, even with additional investments, to enhance interconnections and storages capacities, demand cannot be totally satisfied in 2040. Extra production or imports need to be added by 2040 to cover total demand for both infrastructure levels.

Moreover, when comparing with the unlimited imports scenario, where it seems to not give much extra benefits, it confirms that internal bottlenecks are the limitation to enable flow to go from different supply sources to demand.

By comparing the integration of electrolyzers production is evident that the bottlenecks are limiting the integration of power generation in the system.

This integration of electrolyzers production is also valid for all other production sources.

7.2.3 IDENTIFICATION OF PROJECTS THAT SOLVED OR MITIGATED INFRASTRUCTURE GAPS

Solved infrastructure gaps in Advanced hydrogen infrastructure level compared to PCI/PMI hydrogen infrastructure level

The additional projects of the advanced infrastructure level could solve the following indications of regional hydrogen infrastructure gaps:

- ▲ Borders as captured by IGI indicator 1: None.
- ▲ Countries and regions as captured by IGI indicator 2.1: None.

- ▲ Countries and regions as captured by IGI indicator 2.2: Slovakia-West.

Not all IGI indicators could be solved from a regional perspective even if the advanced hydrogen projects provide benefits.

Identification of advanced, non-PCI/PMI projects responsible for solving hydrogen infrastructure gaps by addressing hydrogen infrastructure bottlenecks

The following advanced, non-PCI/PMI projects contributed to mitigate the identified infrastructure gaps in the 2040 assessment:

- ▲ Pipeline imports: All pipeline imports available in both infrastructure levels.
 - Slovakia to Hungary (HU/SK hydrogen corridor and SK-HU H₂ corridor)
 - Hungary to Romania (Giurgiu Nădlac hydrogen corridor and HU/RO hydrogen corridor)
 - Netherlands to Germany (H2Coastlink, IP Elten/Zevenaar – Cologne, Hyperlink and H2ercules Network North-West)
 - Germany to Poland (Pomeranian Green Hydrogen Cluster)
 - Hungary to Romania (Giurgiu Nădlac hydrogen corridor and HU/RO hydrogen corridor)
 - Romania to Hungary (Giurgiu Nădlac hydrogen corridor and HU/RO hydrogen corridor)

- ▲ Import terminals
 - New Ammonia terminal in Gdansk and Hydrogen Highway – Northern Section
 - Increased terminal capacity in the Netherlands (Eemshaven H₂)
- ▲ Hydrogen storages
 - Hydrogen storage projects in Germany (RWE H₂ Storage Gronau-Epe, UST Hydrogen Storage Krummhörn, RWE H₂ Storage Xanten, EWE Hydrogen Storage Huntorf, EWE Hydrogen Storage Jemgum, RWE H₂ Storage Staßfurt, EWE Hydrogen Storage Huntorf)
 - Hydrogen storage project in the France-Southwest region of France (HySoW storage)

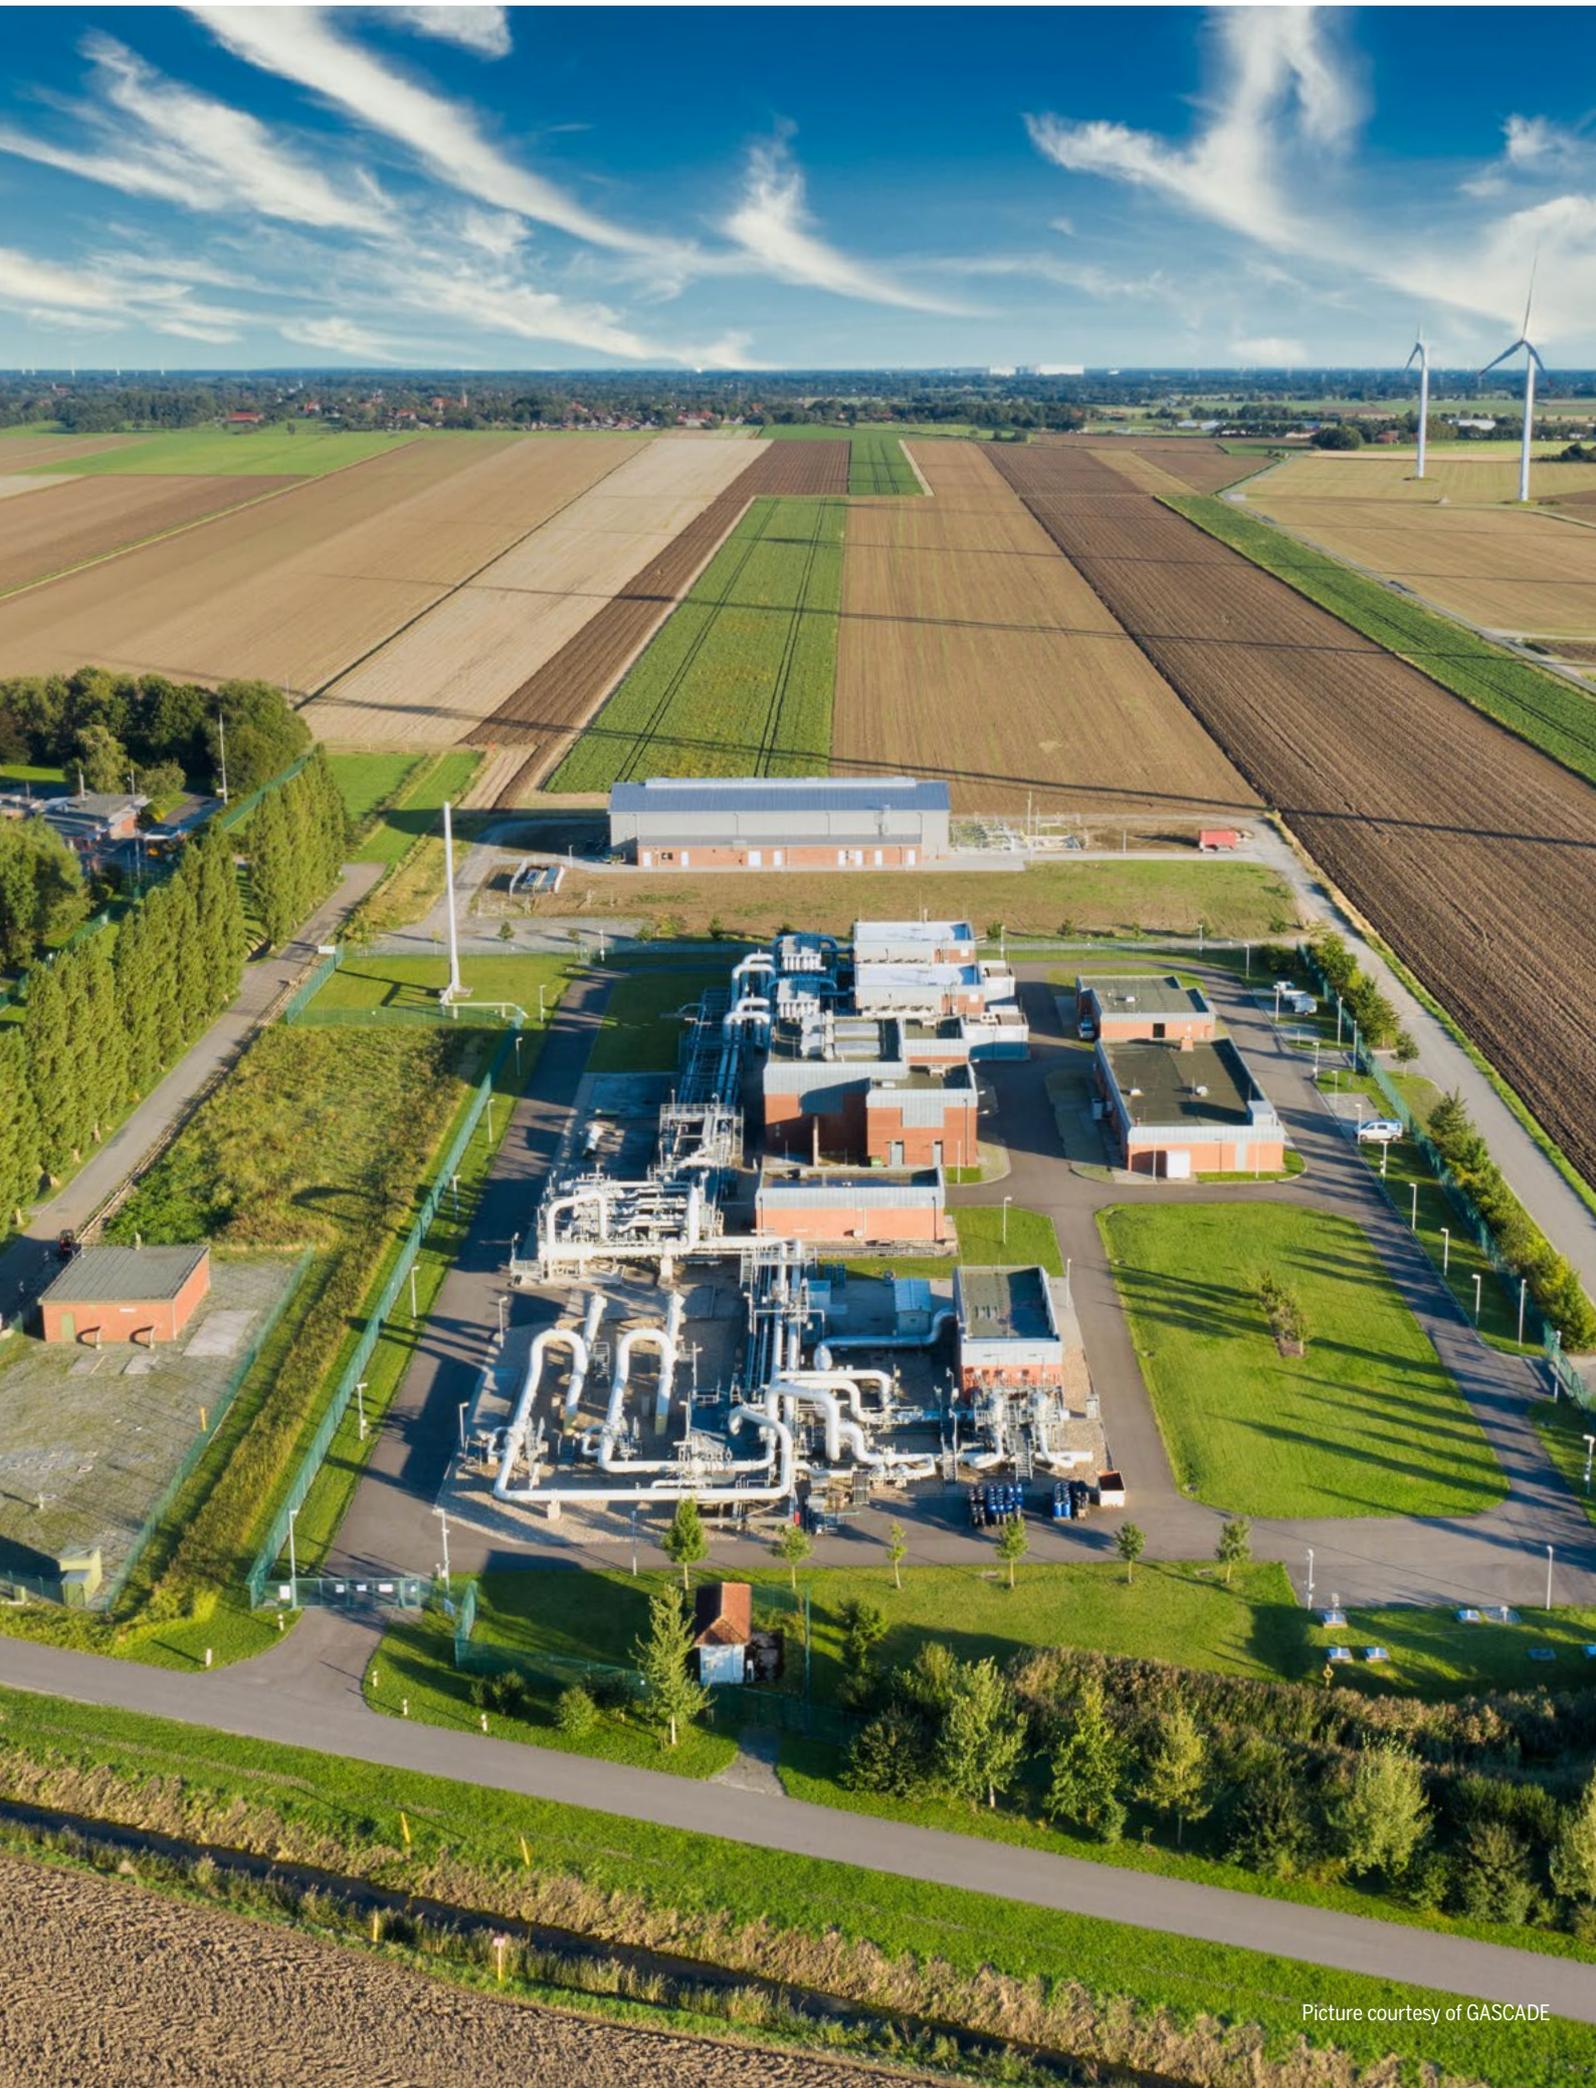

Besides the projects listed above, the projects included in the PCI/PMI hydrogen infrastructure level also contribute to the solving and mitigation of infrastructure gaps.

8 CONCLUSIONS

This IGI report provides the following main insights:

- ▲ Observed hydrogen demand satisfaction and hydrogen price convergence in Europe are enabled by the projects that are included in the respective hydrogen infrastructure levels.
- ▲ Every simulation showed hydrogen demand curtailments in Europe, especially in winter.
- ▲ Supply and infrastructure in the two hydrogen infrastructure levels are not sufficient on European level. This is indicated by the IGI indicators.
- ▲ All European hydrogen corridors considered in the assessments are needed to satisfy hydrogen demand.
- ▲ Hydrogen pipelines and storages help to mitigate hydrogen demand curtailments.
- ▲ Hydrogen infrastructure bottlenecks exist and are explained in the report.
- ▲ Due to the effect of the weather on the demand/supply balance of hydrogen, the European hydrogen backbone benefits from flexibilities in the supply, storage, and transit infrastructure.
- ▲ Several countries, especially islands and countries in South-East Europe, are not connected to the European hydrogen backbone in one or both hydrogen infrastructure levels.
- ▲ Isolated countries benefit from new connections with the European hydrogen backbone.
- ▲ Many projects represent anticipatory investments. They are not fully utilised in 2030 but show high utilisation in 2040. This allows to unlock the significant economies of scale of hydrogen infrastructure projects.
- ▲ Even projects that are currently defined as less advanced, especially if increasing exports towards curtailed countries, will be needed.

Thereby, this IGI report is based on the TYNDP 2024 NT+ scenario and the projects submitted to the TYNDP 2024.

- 1 The electrolyser efficiency is 69% in 2030 and 71% in 2040 in terms of NCV. Therefore, from the perspective of the electricity system, the installed capacity of electrolysers is higher. Here, the installed capacities are stated from the perspective of the hydrogen system and in terms of GCV.
- 2 Each country's total electrolyser and SMR/ATR capacities are specified in the TYNDP 2024 NT+ scenario. In the scenario documentation, the NCV is used to align with EC scenarios. The TYNDP 2024 however uses the GCV as this is commonly used in the gas markets.
- 3 TYNDP 2024 Annex D1 explains i) that project promoters can split Zones into sub-Zones, ii) that a country's electrolyser capacity can undergo a redistribution methodology to allocate electrolyser capacities to (sub-)Zones, and iii) that SMR/ATR capacities for hydrogen production from natural gas are only connected to Zone 1.

LIST OF ABBREVIATIONS

Annex C2	TYNDP 2024 Hydrogen Infrastructure Capacities
Annex D1	TYNDP 2024 Implementation Guidelines
Annex D2	TYNDP 2024 Hydrogen Infrastructure Gaps Identification methodology
d	Day
DGM	Dual Hydrogen/Natural Gas Model or Dual Gas Model
DHEM	Dual Hydrogen/Electricity Model
ENTSO-G	European Network of Transmission System Operators for Gas
ENTSO-E	European Network of Transmission System Operators for Electricity
EU	European Union
ETS	European Union Emissions Trading System
FEED	Front-End Engineering Design
FID	Final Investment Decision
GCV	Gross Calorific Value or Higher Heating Value (25 °C/0 °C)
GWh	Gigawatt Hour
HCR	Hydrogen demand Curtailment Rate
H₂	Hydrogen
IGI	Hydrogen Infrastructure Gaps Identification

IGI indicator 1	Hydrogen Infrastructure Gaps Identification indicator for hydrogen market clearing price spreads
IGI indicator 2.1	Hydrogen Infrastructure Gaps Identification indicator for hydrogen demand curtailment for reference weather year
IGI indicator 2.2	Hydrogen Infrastructure Gaps Identification indicator for hydrogen demand curtailment for stressful weather year
IL	Infrastructure Level
IoSN	ENTSO-E's Identification of System Needs
MW	Megawatt
MWh	Megawatt Hour
NCV	Net Calorific Value or Lower Heating Value (25 °C/0 °C)
NT+	TYNDP 2024 National Trends+ scenario
PCI	Project of Common Interest
PMI	Project of Mutual Interest
RES	Renewable Energy Source(s)

LEGAL DISCLAIMER

The TYNDP was prepared by ENTSOG on the basis of information collected and compiled by ENTSOG from its members and from stakeholders, and on the basis of the methodology developed with the support of the stakeholders via public consultation. The TYNDP contains ENTSOG own assumptions and analysis based upon this information.

All content is provided “as is” without any warranty of any kind as to the completeness, accuracy, fitness for any particular purpose or any use of results based on this information and ENTSOG hereby expressly disclaims all warranties and representations, whether express or implied, including without limitation, warranties or representations of merchantability or fitness for a particular purpose. In particular, the capacity figures of the projects included in TYNDP are based on preliminary assumptions and cannot in any way be interpreted as recognition, by the TSOs concerned, of capacity availability.

ENTSOG is not liable for any consequence resulting from the reliance and/or the use of any information hereby provided, including, but not limited to, the data related to the monetisation of infrastructure impact.

The reader in its capacity as professional individual or entity shall be responsible for seeking to verify the accurate and relevant information needed for its own assessment and decision and shall be responsible for use of the document or any part of it for any purpose other than that for which it is intended.

In particular, the information hereby provided with specific reference to the Projects of Common Interest (“PCIs”) and Projects of Mutual Interest (“PMIs”) is not intended to evaluate individual impact of the PCIs and PMIs and PCI candidates and PMI candidates. For the relevant assessments in terms of value of each PCI and PMI the readers should refer to the information channels or qualified sources provided by law.
