Tariff Methodologies: Examples

Illustrating the document

Public Consultation on Draft Framework Guidelines on rules regarding harmonised transmission tariff structures for gas

Ref: PC_2013_G_03

23rd July 2013
The aim of this document is to illustrate the cost allocation methodologies described in the chapter 3 of the Framework Guidelines for Harmonised Tariff Structures, and allow stakeholders taking part in the Public Consultation to better understand and comment the approach currently envisaged.

All examples depart from a simple network situation, and follow each step of the respective methodologies, as detailed in the draft Framework Guidelines submitted to public consultation.

These examples have been developed for illustration purposes only and cannot take precedence over the principles laid down in the draft Framework Guidelines.

1 Postage stamp

1.1 Inputs on the allowed revenues

i. Allowed revenues: 100 000 €

ii. Capacity/commodity split: 85/15

15% (15 000 €) of the revenue is to be recovered from commodity charge (based on NRA decision).

iii. Entry-exit split: 50/50

42 500 € is allocated to entries, 42 500 € is allocated to exits (including storage entry and exit points, exogenously and ex-ante, based on NRA decision).

iv. Storage discount: 80%

The discount for transmission to and from gas storages is set as 80% of the average fee rate at entry and exit points to and from the transmission system respectively (based on NRA decision).

v. Additional remarks

Total volume of gas fuel planed for transmission: 1.5*10^6 GWh. Commodity charge is being collected at exit points excluding underground storages (NRA decision).

1.2 Transmission network characteristics

Figure 1: Transmission network characteristics - postage stamp
1.3 Main methodology

\( BC_{\Sigma En} \): Booked capacity at entry points
\( BC_{\Sigma Ex} \): Booked capacity at exit points
\( BC_{\Sigma EnST} \): Booked capacity at entry points from gas storages
\( BC_{\Sigma ExST} \): Booked capacity at exit points to gas storages
\( V_{\Sigma Ex} \): Volume of gas to be transmitted
\( S_{\Sigma En/Ex} \): Number of entry and exit points where charge is being collected
\( R_{En} \): Revenue to be collected from entry points
\( R_{Ex} \): Revenue to be collected from exit points
\( R_{EnST} \): Revenue to be collected from entry points from gas storages
\( R_{ExST} \): Revenue to be collected from exit points to gas storages
\( R_{VEx} \): Revenue to be collected from commodity charge
\( R_{SEn/Ex} \): Revenue to be collected from subscription fee

ENTRY CHARGES

\[ T_{En} = \frac{R_{En}}{BC_{\Sigma En}}, \text{ where } T_{En} \text{ is the annual [a] capacity tariff at entry points to the system,} \]

\[ T_{EnST} = \frac{R_{EnST}}{BC_{\Sigma EnST}}, \text{ where } T_{EnST} \text{ is the annual [a] capacity tariff at entry points from gas storages,} \]

while \( (3) T_{EnST} = 0.2 * T_{En} \)

and \( (4) R_{EnST} + R_{En} = 42500 \)

Thus, from (1), (2), (3) and (4):

\[ T_{En} * BC_{\Sigma En} + T_{EnST} * BC_{\Sigma EnST} = 42500 \]

\[ T_{En} * BC_{\Sigma En} + 0.2 * T_{En} * BC_{\Sigma EnST} = 42500 \]

\[ T_{En} = \frac{42500}{BC_{\Sigma En} + 0.2 * BC_{\Sigma EnST}} \]

Example:

\[ T_{En} = \frac{42500}{300 + 400 + 0.2 * 100} = 59.02 \frac{\text{€}}{\text{GWh} / h} \]

---

Footnote:

1 see section 3.4.1.1 of the Revised chapter on Cost Allocation and determination of the reference price
EXIT CHARGES

\[ T_{Ex} = \frac{R_{Ex}}{BC_{\Sigma Ex}} , \text{ where } T_{Ex} \text{ is the annual [a] capacity tariff at exit points from the system,} \]

\[ T_{ExST} = \frac{R_{ExST}}{BC_{\Sigma ExST}} , \text{ where } T_{ExST} \text{ is the annual [a] capacity tariff at exit points to gas storages,} \]

\[ T_{VEx} = \frac{R_{VEx}}{V_{\Sigma Ex}} , \text{ where } T_{VEx} \text{ is the commodity tariff at exit points from the system,} \]

\text{while } T_{ExST} = 0.2 \cdot T_{Ex} \]

\text{and } R_{ExST} + R_{Ex} = 42500 \]

again,

\[ T_{Ex} = \frac{42500}{BC_{\Sigma Ex} + 0.2 \cdot BC_{\Sigma ExST}} \]

Example:

\[ T_{Ex} = \frac{42500}{400 + 100 + 0.2 \cdot 50} = 83.33 \frac{\epsilon}{GWh} \]

\[ T_{ExST} = 0.2 \cdot 83.33 = 16.66 \frac{\epsilon}{GWh} \]

\[ T_{VEx} = \frac{15000}{1500000} = 0.01 \frac{\epsilon}{Gwh} \]
2 Capacity-Weighted Distance approach – Variant A

2.1 Inputs on the allowed revenues

i. Allowed revenues: 100,000 €

ii. Capacity/commodity split: 100/0
   No commodity charge is applied.

iii. Entry-exit split: 50/50
   50% (50,000 €) is allocated to entries, 50% (50,000 €) is allocated to exits (exogenously and ex-ante).

iv. Additional input: booked capacity (see Figure 2 below)
   Entry 1: 7,8
   Entry 2: 13,8
   Entry 3: 25
   Exit 1: 14
   Exit 2: 25

2.2 Transmission network characteristics

![Figure 2 Transmission network characteristics - capacity weighted distance (variant A)](image-url)
2.3 Main methodology

i. Define technical capacity at each entry and exit point; define forecasted booked capacity at each entry and exit point; [define (ex ante) the share of revenue to be collected from entry points and the share of revenue to be collected from exit points].

**General:**

\( C_{Eni} \): Capacity at entry point \( i \)

\( C_{Exj} \): Capacity at exit point \( j \)

\( BC_{Eni} \): Forecasted Booked Capacity at entry point \( i \)

\( BC_{Exj} \): Forecasted Booked Capacity at exit point \( j \)

\( R_{En} \): Revenue to be collected from entry points

\( R_{Ex} \): Revenue to be collected from exit points

**Example:**

\( C_{En1} = 10 \)

\( C_{En2} = 20 \)

\( C_{En3} = 30 \)

\( C_{Ex1} = 20 \)

\( C_{Ex2} = 30 \)

\( BC_{En1} = 7,8 \)

\( BC_{En2} = 13,8 \)

\( BC_{En3} = 25 \)

\( BC_{Ex1} = 14 \)

\( BC_{Ex2} = 25 \)

---

\(^2\) see section 3.4.1.2 of the Revised chapter on Cost Allocation and determination of the reference price
\[ R_{En} = 50.000 \text{ €} \]
\[ R_{Ex} = 50.000 \text{ €} \]

ii. \textbf{Calculate distance between each entry point and each exit point in the system} \(^3\);

\textbf{General:}

\[ D_{En_{i}Ex_{j}} \]: \textit{matrix of the distances from entry} \(i\) \textit{to exit} \(j\)

\textbf{Example:}

\[ D_{En_{1}Ex_{1}} = D_{Ex_{1}En_{1}} = 200 \]
\[ D_{En_{1}Ex_{2}} = D_{Ex_{2}En_{1}} = 300 \]
\[ D_{En_{2}Ex_{1}} = D_{Ex_{1}En_{2}} = 400 \]
\[ D_{En_{2}Ex_{2}} = D_{Ex_{2}En_{2}} = 500 \]
\[ D_{En_{3}Ex_{1}} = D_{Ex_{1}En_{3}} = 600 \]
\[ D_{En_{3}Ex_{2}} = D_{Ex_{2}En_{3}} = 100 \]

iii. \textbf{Calculate the proportion of technical entry (respectively exit) capacity at each point relative to the total technical entry (respectively exit) capacity;}

\textbf{General:}

\[ P_{En_{i}} = \frac{C_{En_{i}}}{\sum C_{En}} \text{ where } P_{En_{i}} \text{ is the proportion factor of entry point } i \]
\[ P_{Ex_{j}} = \frac{C_{Ex_{j}}}{\sum C_{Ex}} \text{ where } P_{Ex_{j}} \text{ is the proportion factor of exit point } j \]

\textbf{Example:}

\[ P_{En_{1}} = \frac{C_{En_{1}}}{C_{En_{1}} + C_{En_{2}} + C_{En_{3}}} = \frac{10}{10 + 20 + 30} = \frac{1}{6} \]
\[ P_{En_{2}} = \frac{C_{En_{2}}}{C_{En_{1}} + C_{En_{2}} + C_{En_{3}}} = \frac{20}{10 + 20 + 30} = \frac{1}{3} \]
\[ P_{En_{3}} = \frac{C_{En_{3}}}{C_{En_{1}} + C_{En_{2}} + C_{En_{3}}} = \frac{30}{10 + 20 + 30} = 0,5 \]

\(^3\) this can be done by calculating the shortest distance from each entry point to each exit point
iv. For each entry point (respectively exit point), calculate capacity-weighted average distance to all exit points (respectively entry points); average distance is weighted by technical capacity

**General:**

\[ AD_{En_i} = \sum P_{En_j} \times D_{En_i, En_j} \] where \( AD_{En_i} \) is the capacity weighted average distance from entry \( i \)

\[ AD_{Ex_j} = \sum P_{En_i} \times D_{Ex_j, En_i} \] where \( AD_{Ex_j} \) is the capacity weighted average distance from exit \( j \)

**Example:**

Capacity Weighted Average Distance from Entry 1 to all Exits:

\[ AD_{En_1} = P_{Ex_1} \times D_{En_1, En_1} + P_{Ex_2} \times D_{En_1, En_2} = 0.4 \times 200 + 0.6 \times 300 = 260 \]

Capacity Weighted Average Distance from Entry 2 to all Exits:

\[ AD_{En_2} = ... = 460 \]

Capacity Weighted Average Distance from Entry 3 to all Exits:

\[ AD_{En_3} = ... = 300 \]

Capacity Weighted Average Distance from Exit 1 to all Entries:

\[ AD_{Ex_1} = P_{En_1} \times D_{Ex_1, En_1} + P_{En_2} \times D_{Ex_1, En_2} + P_{En_3} \times D_{Ex_1, En_3} = \frac{1}{6} \times 200 + \frac{1}{3} \times 400 + 0.5 \times 600 = 466.67 \]

Capacity Weighted Average Distance from Exit 2 to all Entries:

\[ AD_{Ex_2} = ... = \frac{1}{6} \times 200 + \frac{1}{3} \times 400 + 0.5 \times 600 = 266.67 \]

v. Determine the weight of each entry point (respectively exit point) as the ratio between the product of its technical capacity with its average distance and the sums of such products for all entry points (respectively exit point)

**General:**

\[ W_{En_i} = \frac{C_{En_i} \times AD_{En_i}}{\sum C_{En_i} \times AD_{En_i}} \] where \( W_{En_i} \) is the weight of entry point \( i \)
\[ W_{EX_j} = \frac{C_{EX_j} \times AD_{EX_j}}{\sum C_{EX_j} \times AD_{EX_j}} \text{ where } W_{EX_j} \text{ is the weight of exit point } j \]

**Example:**

The products of capacity and average distance are:

\[ C_{En_1} \times AD_{En_1} = 10 \times 260 = 2,600 \]
\[ C_{En_2} \times AD_{En_2} = 20 \times 460 = 9,200 \]
\[ C_{En_3} \times AD_{En_3} = 30 \times 300 = 9,000 \]
\[ C_{Ex_1} \times AD_{Ex_1} = 20 \times 466,67 = 9,333,33 \]
\[ C_{Ex_2} \times AD_{Ex_2} = 30 \times 266,67 = 8,000 \]

\[ W_{En_1} = \frac{C_{En_1} \times AD_{En_1}}{C_{En_1} \times AD_{En_1} + C_{En_2} \times AD_{En_2} + C_{En_3} \times AD_{En_3}} = \frac{2,600}{2,600 + 9,200 + 9,000} = 0,125 \]
\[ W_{En_2} = \frac{C_{En_2} \times AD_{En_2}}{C_{En_1} \times AD_{En_1} + C_{En_2} \times AD_{En_2} + C_{En_3} \times AD_{En_3}} = \frac{9,200}{2,600 + 9,200 + 9,000} = 0,442 \]
\[ W_{En_3} = \frac{C_{En_3} \times AD_{En_3}}{C_{En_1} \times AD_{En_1} + C_{En_2} \times AD_{En_2} + C_{En_3} \times AD_{En_3}} = \frac{9,000}{2,600 + 9,200 + 9,000} = 0,433 \]
\[ W_{Ex_1} = \frac{C_{Ex_1} \times AD_{Ex_1}}{C_{Ex_1} \times AD_{Ex_1} + C_{Ex_2} \times AD_{Ex_2}} = \frac{9,333,33}{9,333,33 + 8,000} = 0,538 \]
\[ W_{Ex_2} = \frac{C_{Ex_2} \times AD_{Ex_2}}{C_{Ex_1} \times AD_{Ex_1} + C_{Ex_2} \times AD_{Ex_2}} = \frac{8,000}{9,333,33 + 8,000} = 0,462 \]

vi. **Allocate entry cost (respectively exit costs) by multiplying the total revenue to be collected from entry points by the weight of each entry point (respectively exit point)**

**General:**
\[ R_{En_i} = W_{En_i} \times R_{En} \text{ where } R_{En_i} \text{ is the revenue to be collected from entry point } i \]
\[ R_{Ex_j} = W_{Ex_j} \times R_{Ex} \text{ where } R_{Ex_j} \text{ is the revenue to be collected from exit point } j \]

**Example:**
\[ R_{En_1} = W_{En_1} \times R_{En} = 0,125 \times 50.000€ = 6.250,00 € \]
\[ R_{En_2} = W_{En_2} \times R_{En} = 0,442 \times 50.000€ = 22.115,38 € \]
\[ R_{En_3} = W_{En_3} \times R_{En} = 0,433 \times 50.000€ = 21.634,62 € \]
vii. Determine tariffs by dividing revenue to be collected from a point by its forecasted booked capacity

General:

\[ T_{En_i} = \frac{R_{En_i}}{BC_{En_i}} \text{ where } T_{En_i} \text{ is the tariff at entry point } i \]
\[ T_{Ex_j} = \frac{R_{Ex_j}}{BC_{Ex_j}} \text{ where } T_{En_i} \text{ is the tariff at exit point } i \]

Example:

\[ T_{En_1} = \frac{R_{En_1}}{BC_{En_1}} = \frac{6.250}{7.8} = 801.28 \frac{\text{€}}{\text{kWh}} / \text{a} \]
\[ T_{En_2} = \frac{R_{En_2}}{BC_{En_2}} = \frac{22.100}{13.8} = 1.602.56 \frac{\text{€}}{\text{kWh}} / \text{a} \]
\[ T_{En_3} = \frac{R_{En_3}}{BC_{En_3}} = \frac{21.650}{25} = 866.38 \frac{\text{€}}{\text{kWh}} / \text{a} \]
\[ T_{Ex_1} = \frac{R_{Ex_1}}{BC_{Ex_1}} = \frac{26.900}{14} = 1.923.08 \frac{\text{€}}{\text{kWh}} / \text{a} \]
\[ T_{Ex_2} = \frac{R_{Ex_2}}{BC_{Ex_2}} = \frac{23.100}{25} = 923.08 \frac{\text{€}}{\text{kWh}} / \text{a} \]

Alternatively, step 5 can be executed in a similar way by relying on forecasted booked capacity. In a first step (steps 1-4), capacity weighted average distance is calculated based on technical capacity. In a second step, costs are/revenue is allocated considering forecasted booked capacity: the weight of each point is determined by using forecasted booked capacity, not technical capacity. This is justified by the fact that only a part of the technical capacity is booked and that network load is rather based on booked capacities than on technical capacity.

v. Determine the weight of each entry point (respectively exit point) as the ratio between the product of its forecasted booked capacity with its average distance and the sums of such products for all entry points (respectively exit point)

General:

\[ W_{En_i} = \frac{BC_{En_i} \times AD_{En_i}}{\sum BC_{En_i} \times AD_{En_i}} \text{ where } W_{En_i} \text{ is the weight of entry point } i \]
\[ W_{Ex_j} = \frac{BC_{Ex_j} \times AD_{Ex_j}}{\sum BC_{Ex_j} \times AD_{Ex_j}} \text{ where } W_{Ex_j} \text{ is the weight of exit point } j \]

Example:
The products of capacity and average distance are:

\[ BC_{En_1} \times AD_{En_1} = 7.8 \times 260 = 2.028 \]

\[ BC_{En_2} \times AD_{En_2} = 13.8 \times 460 = 6.348 \]

\[ BC_{En_3} \times AD_{En_3} = 25 \times 300 = 7.500 \]

\[ BC_{Ex_1} \times AD_{Ex_1} = 14 \times 466.67 = 6.533,33 \]

\[ BC_{Ex_2} \times AD_{Ex_2} = 25 \times 266.67 = 6.666,67 \]

\[
W_{En_1} = \frac{BC_{En_1} \times AD_{En_1}}{BC_{En_1} \times AD_{En_1} + BC_{En_2} \times AD_{En_2} + BC_{En_3} \times AD_{En_3}} = \frac{2028}{2028 + 6348 + 7500} = 0,128
\]

\[
W_{En_2} = \frac{BC_{En_2} \times AD_{En_2}}{BC_{En_1} \times AD_{En_1} + BC_{En_2} \times AD_{En_2} + BC_{En_3} \times AD_{En_3}} = \frac{6348}{2028 + 6348 + 7500} = 0,400
\]

\[
W_{En_3} = \frac{BC_{En_3} \times AD_{En_3}}{BC_{En_1} \times AD_{En_1} + BC_{En_2} \times AD_{En_2} + BC_{En_3} \times AD_{En_3}} = \frac{7500}{2028 + 6348 + 7500} = 0,472
\]

\[
W_{Ex_1} = \frac{BC_{Ex_1} \times AD_{Ex_1}}{BC_{Ex_1} \times AD_{Ex_1} + BC_{Ex_2} \times AD_{Ex_2}} = \frac{6533,33}{6533,33 + 6666,67} = 0,495
\]

\[
W_{Ex_2} = \frac{BC_{Ex_2} \times AD_{Ex_2}}{BC_{Ex_1} \times AD_{Ex_1} + BC_{Ex_2} \times AD_{Ex_2}} = \frac{6666,67}{6533,33 + 6666,67} = 0,505
\]

vi. Allocate entry cost (respectively exit costs) by multiplying the total revenue to be collected from entry points by the weight of each entry point (respectively exit point)

General:
\[ R_{En_i} = W_{En_i} \times R_{En} \] where \( R_{En_i} \) is the revenue to be collected from entry point \( i \)

\[ R_{Ex_j} = W_{Ex_j} \times R_{Ex} \] where \( R_{Ex_j} \) is the revenue to be collected from exit point \( j \)

Example:
\[ R_{En_1} = W_{En_1} \times R_{En} = 0,128 \times 50.000 \text{€} = 6.387,00 \text{€} \]
\[ R_{En_2} = W_{En_2} \times R_{En} = 0,400 \times 50.000 \text{€} = 19.992,44 \text{€} \]
\[ R_{En_3} = W_{En_3} \times R_{En} = 0,472 \times 50.000 \text{€} = 23.620,56 \text{€} \]
\[ R_{Ex_1} = W_{Ex_1} \times R_{Ex} = 0,495 \times 50.000 \text{€} = 24.747,47 \text{€} \]
\[ R_{Ex_2} = W_{Ex_2} \times R_{Ex} = 0,505 \times 50.000 \text{€} = 25.252,53 \text{€} \]
vii. Determine tariffs by dividing revenue to be collected from a point by its forecasted booked capacity,

General:

\[ T_{\text{En}_i} = \frac{R_{\text{En}_i}}{BC_{\text{En}_i}} \text{ where } T_{\text{En}_i} \text{ is the tariff at entry point } i \]

\[ T_{\text{Ex}_j} = \frac{R_{\text{Ex}_j}}{BC_{\text{Ex}_j}} \text{ where } T_{\text{Ex}_j} \text{ is the tariff at exit point } j \]

Example:

\[ T_{\text{En}_1} = \frac{R_{\text{En}_1}}{BC_{\text{En}_1}} = \frac{6.387}{7.8} = 818.85 \frac{\epsilon}{\text{kWh/h}} / a \]

\[ T_{\text{En}_2} = \frac{R_{\text{En}_2}}{BC_{\text{En}_2}} = \frac{19.992}{13.8} = 1.448.73 \frac{\epsilon}{\text{kWh/h}} / a \]

\[ T_{\text{En}_3} = \frac{R_{\text{En}_3}}{BC_{\text{En}_3}} = \frac{23.621}{25} = 944.82 \frac{\epsilon}{\text{kWh/h}} / a \]

\[ T_{\text{Ex}_1} = \frac{R_{\text{Ex}_1}}{BC_{\text{Ex}_1}} = \frac{24.747}{14} = 1.767.68 \frac{\epsilon}{\text{kWh/h}} / a \]

\[ T_{\text{Ex}_2} = \frac{R_{\text{Ex}_2}}{BC_{\text{Ex}_2}} = \frac{25.253}{25} = 1.010.10 \frac{\epsilon}{\text{kWh/h}} / a \]
3 Capacity-Weighted Distance approach – Variant B

3.1 Inputs on the allowed revenues

i. Allowed revenue: 500 000 000 €

ii. Entry-exit split: the Entry-Exit split results from the methodology (see below)

</table>
4 Virtual point-based approach – Variant A

4.1 Inputs on the allowed revenues

i. Allowed revenues: 100m €
   In this example this is not used to calculate the marginal cost, however, the allowed revenues will be factored into the tariff setting process as a secondary step by means of rescaling the tariffs to recover allowed revenue.

ii. Entry-exit split: 50/50
   50% is allocated to entries, 50% is allocated to exits (exogenously and ex-ante).

4.2 Transmission network characteristics

![Figure 4: Transmission network characteristics - distance to the virtual point (variant A)](image-url)
4.3 Main methodology\(^5\)

i. A network representation is developed and divided into segments. See Figure 4.

ii. Capacity used at peak at each of these segments is then identified.

If total peak demand is X GWh then we use the entry flow assumptions to find out how much flows from each entry point so that total entry flows equals X GWh. The entry flow assumptions are developed in a separate process, which may be in the form of a list of entry points which order where gas flows from i.e. a merit order. We find the network capacity used at peak by minimising the flow multiplied by the distance (i.e. flow distance) for the whole network such that the peak exit flows (X GWh) is matched by the individual entry flows as set above. This gives a flow distance and the direction of flow for each segment. In Figure 4, the values in yellow show these flow distances (and the arrows the direction of flow) after this minimisation has been completed.

iii. Next we calculate the marginal distance for each point to/from a reference node.

Building on the above scenario, we then arbitrarily select a reference node on the network and consider the flow distances of a marginal unit of gas (in our worked example one unit). In the worked example we select node n2 and sum the flow distances at peak (in the diagram) for a marginal unit of gas at each entry point to the reference node (and exit point from the reference node) for each exit point in turn. For example, a marginal unit of gas flowing from Entry A to reference node n2 has a flow distance of 21 GWhkm. From Entry Point C to the reference node the marginal flow distance is -9 GWhkm. This is because it has a flow distance of 1 GWhkm from Entry Point C to n3, and 10 GWhkm from n3 to n2. As this requires a flow from n3 to n2 which is against the direction of flow at peak then it is represented as a negative flow distance.

iv. Completing this for all points, gives you the flow distance values (in GWhkm)

The flow distance values for all points are specified in the yellow boxes Figure 5 below. The purple boxes indicate the flow distance to travel from all entry to all exit point combinations via the reference node. As this looks at the flow distance for a single marginal unit of flow in GWh the values in the table also show the value of the marginal distance (which is equal to the flow distance divided by the difference in flow of the marginal unit).

---

\(^5\) see section 3.4.1.3 of the Revised chapter on Cost Allocation and determination of the reference price
v. As the reference node is chosen arbitrarily we now adjust for the virtual point

This step is done so that average distance for entry and exit points reflects the entry exit split and so locates the virtual point. This is done by taking the marginal distances for entry and adding a constant to each and taking the marginal distances for exit and subtracting the same constant.

To establish what the constant (\(d\)) is when we want a 50:50 entry split we must solve the following equation (note that when determining this constant we do not consider those points where those marginal distances plus or minus that constant are negative):

\[
Split_{en} \cdot \frac{\sum \max(0, en_i + d)}{N_i} = Split_{ex} \cdot \frac{\sum \max(0, ex_j - d)}{N_j}
\]

Solve for \(d\), where:
- \(Split_{en}\) is the share of revenue to be collected from entry points (assume 50%)
- \(Split_{ex}\) is the share of revenue to be collected from entry points (assume 50%)
- \(en_i\) is the marginal distance for all entry points \(i\)
- \(ex_j\) is the marginal distance for all exit points \(j\)
- \(N_i\) is the number of entry points
- \(N_j\) is the number of entry points
- \(d\) is the constant factor to adjust the marginal distances
0.5 \times \left[ \frac{\max[0, (21 + d)] + \max[0, (10 + d)] + \max[0, (-9 + d)]}{3} \right] \\
= 0.5 \times \left[ \frac{\max[0, (11 - d)] + \max[0, (3 - d)] + \max[0, (-19 - d)]}{4} \right] \\
\frac{(21 + d) + (10 + d)}{3} = \frac{(11 - d) + (3 - d) + (3 - d)}{4} \\
4[21+d+10+d] = 3[11-d+3-d+3-d] \\
4(31+2d) = 3(17-3d) \\
124+8d = 51-9d \\
17d = -73 \\
This gives a value for (d) of 4.3.

vi. Adding the constant (d) to all entry points, and subtracting from exit points gives us the new values in Figure 6.

Note the points (in the purple section) which show marginal distance between all entry points is unchanged.

<table>
<thead>
<tr>
<th>Entry A</th>
<th>Entry B</th>
<th>Entry C</th>
</tr>
</thead>
<tbody>
<tr>
<td>16.7</td>
<td>5.7</td>
<td>-13.3</td>
</tr>
</tbody>
</table>

![Figure 6: flow distance values after adjustment of the reference node](image)

vii. To set our tariffs, the unit cost per entry and exit point we multiply the marginal distance at all entry and exit points in Figure 6 by the expansion constant and annuitisation factor.

Assuming an expansion constant of 1.5 (£m/GWhkm) and an annuitisation factor of 0.9. For exit point 1 therefore the tariff would be: 15.3*0.9*1.5 = 20.7 £/GWh. Complete this process for all points.
5  Virtual point-based approach – Variant B

5.1  Inputs on the allowed revenues

i.  **Allowed revenue**: 1000

ii.  **Entry/exit split**: this is an outcome of the methodology (see below)

5.2  Transmission network characteristics

![Diagram showing transmission network characteristics distance to the virtual point (variant B)]

**Figure 7**: Transmission network characteristics - distance to the virtual point (variant B)

T ... Technical capacity

B ... Booked capacity

5.3  Main methodology

i.  Define capacity at each entry and exit point:

\[ C_E^i \]: Technical capacity at entry point \( i \)

\[ C_X^j \]: Technical capacity at exit point \( j \)

---

6 see section 3.4.1.3 of the Revised chapter on Cost Allocation and determination of the reference price
BC_{Ei}: Booked capacity at entry point i

BC_{Xi}: Booked capacity at exit point j

Technical Capacities:

Entry 1: \( C_{E1} = 350 \)
Entry 2: \( C_{E2} = 30 \)
Exit 1: \( C_{X1} = 150 \)
Exit 2: \( C_{X2} = 30 \)
Exit D1: \( C_{XD1} = 100 \) (domestic exit)
Exit D2: \( C_{XD2} = 10 \) (domestic exit)

Booked Capacities:

Entry 1: \( BC_{E1} = 200 \)
Entry 2: \( BC_{E2} = 20 \)
Exit 1: \( BC_{X1} = 120 \)
Exit 2: \( BC_{X2} = 20 \)
Exit D1: \( BC_{XD1} = 80 \)
Exit D2: \( BC_{XD2} = 10 \)

ii. Determine the geographical location of the virtual trading point:

The virtual point can be determined geographically by selecting a dominant node in the network where most flows occur. The virtual point can be also determined geographically based on the capacity weighted average geographical locations of all entry and exit points.

a. Calculate the proportion of entry (or exit) capacity at each point relative to the total entry and exit capacity:

\[
P_{Ei} = \frac{C_{Ei}}{\sum C_{E} + \sum C_{X}} \text{ where } P_{Ei} \text{ is the proportion factor of entry point } i
\]
\[ P_{X_j} = \frac{C_{X_j}}{\sum C_E + \sum C_X} \text{ where } P_{X_j} \text{ is the proportion factor of exit point } j \]

\[ P_{E_1} = \frac{C_{E_1}}{\sum C_E + \sum C_X} = \frac{350}{350+30+150+30+100+10} = 0.522 \]

\[ P_{E_2} = \frac{C_{E_2}}{\sum C_E + \sum C_X} = \frac{30}{350+30+150+30+100+10} = 0.045 \]

\[ P_{X_1} = \frac{C_{X_1}}{\sum C_E + \sum C_X} = \frac{150}{350+30+150+30+100+10} = 0.224 \]

\[ P_{X_2} = \frac{C_{X_2}}{\sum C_E + \sum C_X} = \frac{30}{350+30+150+30+100+10} = 0.045 \]

\[ P_{XD_1} = \frac{C_{XD_1}}{\sum C_E + \sum C_X} = \frac{100}{350+30+150+30+100+10} = 0.149 \]

\[ P_{XD_2} = \frac{C_{XD_2}}{\sum C_E + \sum C_X} = \frac{10}{350+30+150+30+100+10} = 0.015 \]

b. Multiply the geographical locations (longitude and latitude) of each entry (and exit) point with its proportion factor:

\[ L_{E_i} = [\text{long}_{E_i} \times P_{E_i}; \text{lat}_{E_i} \times P_{E_i}], \]

where \( L_{E_i} \) is the capacity weighted geographic location of entry point \( i \)

\[ L_{X_j} = [\text{long}_{X_j} \times P_{X_j}; \text{lat}_{X_j} \times P_{X_j}], \]

where \( L_{X_j} \) is the capacity weighted geographic location of exit point \( j \)

\[ L_{E_1} = [12.80 \times 0.522; 47.83 \times 0.522] = [6.68; 24.97] \]

\[ L_{E_2} = [14.30 \times 0.045; 48.24 \times 0.045] = [0.64; 2.17] \]

\[ L_{X_1} = [15.42 \times 0.224; 46.98 \times 0.224] = [3.45; 10.52] \]

\[ L_{X_2} = [15.66 \times 0.045; 48.19 \times 0.045] = [0.70; 2.17] \]

\[ L_{XD_1} = [13.07 \times 0.149; 47.73 \times 0.149] = [1.95; 7.11] \]

\[ L_{XD_2} = [14.06 \times 0.015; 48.04 \times 0.015] = [0.21; 0.72] \]

c. Summing of the capacity weighted geographic locations to determine location of the virtual point:

\[ L_{VP} = \sum L_E + \sum L_X \text{ where } L_{VP} \text{ is the location of the virtual point} \]
After summing the capacity weighted geographic locations of all entry and exit points, the location of the virtual point is determined to be at the following coordinates:

\[ L_{VP} = [13.64; 47.66] \]

iii. Calculate distance between each entry point and the virtual point as well as each exit point and the virtual point:

\[ D_{E_{i,VP}}: \text{distance from entry point } i \text{ to } VP \]
\[ D_{X_{j,VP}}: \text{distance from exit point } j \text{ to } VP \]

Entry 1: \( D_{E_{1,VP}} = 106.03 \)
Entry 2: \( D_{E_{2,VP}} = 45.84 \)
Exit 1: \( D_{X_{1,VP}} = 131.27 \)
Exit 2: \( D_{X_{2,VP}} = 114.44 \)
Exit D1: \( D_{X_{D1,VP}} = 86.30 \)
Exit D2: \( D_{X_{D2,VP}} = 25.97 \)

Note: several approaches to distance calculation are possible. The one applied here is as follows:

- take the latitude and longitude (in degrees) of each point and convert it to radians.
- calculate the average of all latitudes and the average of all longitudes (this is in radians as well)
- then use the following formula for each point:
  \[ (ARCCOS(SIN(LatitudePoint1) \times SIN(AverageLatitude) + COS(LatitudePoint1) \times COS(AverageLatitude) \times COS(AverageLongitude - LongitudePoint1))) \times 6378.137 \]
  with 6378.137 = equatorial radius in kilometers

iv. Calculate the capacity-weighted distance to the virtual point to determine the entry-exit split and the revenue to be collected from all entry points and all exit points:

a. Calculate the capacity-weighted distance to the virtual point for entry and exit points separately

\[ DC_{E_{i,VP}} = D_{E_{i,VP}} \times \frac{C_{E_i}}{\sum C_E} ; \]

where \( DC_{E_{i,VP}} \) is the capacity-weighted distance from entry point \( i \) to the virtual point
\[ DC_{XVP} = D_{XVP} \times \frac{C_{Xj}}{\sum C_X}; \]

where \( DC_{XVP} \) is the capacity-weighted distance from exit point \( j \) to the virtual point \( X \).

\[ DC_{E1VP} = D_{E1VP} \times \frac{C_{E1}}{\sum C_E} = 106,03 \times \frac{350}{350 + 30} = 97,66 \]

\[ DC_{E2VP} = D_{E2VP} \times \frac{C_{E2}}{\sum C_E} = 45,84 \times \frac{30}{350 + 30} = 3,62 \]

\[ DC_{X1VP} = D_{X1VP} \times \frac{C_{X1}}{\sum C_X} = 131,27 \times \frac{150}{150 + 30 + 100 + 10} = 67,90 \]

\[ DC_{X2VP} = D_{X2VP} \times \frac{C_{X2}}{\sum C_X} = 114,44 \times \frac{30}{150 + 30 + 100 + 10} = 11,84 \]

\[ DC_{XD1VP} = D_{XD1VP} \times \frac{C_{XD1}}{\sum C_X} = 86,30 \times \frac{100}{150 + 30 + 100 + 10} = 29,76 \]

\[ DC_{XD2VP} = D_{XD2VP} \times \frac{C_{XD2}}{\sum C_X} = 25,97 \times \frac{10}{150 + 30 + 100 + 10} = 0,90 \]

b. Use the sum of capacity-weighted distances for entry points and the sum of capacity-weighted distances for exit points to determine the Entry-Exit split

\[ \frac{\sum DC_{EVP}}{\sum DC_{EVP} + \sum DC_{XVP}} = %E; \]

where \( %E \) is the percentage of revenue collected at entry points in an Entry-Exit system.

\[ \frac{\sum DC_{XVP}}{\sum DC_{EVP} + \sum DC_{XVP}} = %X; \]

where \( %X \) is the percentage of revenue collected at exit points in an Entry-Exit system.

\[ \frac{\sum DC_{EVP}}{\sum DC_{EVP} + \sum DC_{XVP}} = \frac{101,28}{101,28 + 110,39} = 0,48 \]

\[ \frac{\sum DC_{XVP}}{\sum DC_{EVP} + \sum DC_{XVP}} = \frac{110,39}{101,28 + 110,39} = 0,52 \]

c. Calculate the revenue collected from all entry points as well as the revenue collected from all exit points

Assuming revenue \( R \) to be 1000:
\[ R_E = 1000 \times \%E = 478.47; \] 
where \( R_E \) is the revenue collected from all entry points

\[ R_X = 1000 \times \%X = 521.53; \] 
where \( R_X \) is the revenue collected from all exit points

v. Determine tariffs by minimizing the difference between the calculated revenue from entries and exits on the one hand and the revenue to be obtained by multiplying tariffs by booked capacities on the other hand:

a. By selecting one entry point as a reference, set the ratio of the tariffs for entry points to be the same as the ratio of the distances between these entry points and the virtual point. Use the same methodology for exit points.

Selecting Entry 2 and Exit D2 as references:

\[ RT_{E_1} = \frac{D_{E_1,VP}}{D_{E_2,VP}} = \frac{106.03}{45.84} = 2.31; \]
where \( RT_{E_1} \) is the tariff ratio between Entry 1 and the reference Entry (Entry 2)

\[ RT_{E_2} = 1 \]

\[ RT_{X_1} = \frac{D_{X_1,VP}}{D_{X_2,VP}} = \frac{131.27}{25.97} = 5.05; \]
where \( RT_{X_1} \) is the tariff ratio between Exit 1 and the reference Exit (Exit D2)

\[ RT_{X_2} = \frac{D_{X_2,VP}}{D_{X_2,VP}} = \frac{114.44}{25.97} = 4.41; \]
where \( RT_{X_2} \) is the tariff ratio between Exit 2 and the reference Exit (Exit D2)

\[ RT_{XD_1} = \frac{D_{XD_1,VP}}{D_{XD_2,VP}} = \frac{86.30}{25.97} = 3.32; \]
where \( RT_{XD_1} \) is the tariff ratio between Exit D1 and the reference Exit (Exit D2)

\[ RT_{XD_2} = 1 \]

b. Set the reference point (Entry 2 and Exit D2) tariffs to 1 and then calculate the tariffs at other points by using the ratios determined in the previous step.

\[ T_{E_1} = 2.31 \times T_{E_2}; \]
where \( T_{E_1} \) is the tariff at entry point 1 and \( T_{E_2} \) the tariff at entry point 2

\[ T_{X_1} = 5.05 \times T_{XD_2}; \]
where \( T_{X_1} \) is the tariff at exit point 1 and \( T_{XD_2} \) the tariff at exit point D2

\[ T_{X_2} = 4.41 \times T_{XD_2}; \]
where \( T_{X_2} \) is the tariff at exit point 2 and \( T_{XD_2} \) the tariff at exit point D2

\[ T_{XD_1} = 3.32 \times T_{XD_2}; \]
where \( T_{XD_1} \) is the tariff at exit point D1 and \( T_{XD_2} \) the tariff at exit point D2
c. Calculate the revenue collected at every point by multiplying tariffs by booked capacities. Use this result to adjust the tariffs to minimise the difference between combined revenue from all entry points and the revenue $R_E$ calculated in step 4c. Repeat the step for exit points.

Setting $T_{E_2}$ to 0,99:

$$REV_{E_2} = T_{E_2} \times BC_{E_2} = 0,99 \times 20 = 19,80;$$  
where $REV_{E_2}$ is the revenue collected at entry point 2

Then,

$$T_{E_1} = 2,31 \times T_{E_2} = 2,29$$

$$REV_{E_1} = T_{E_1} \times BC_{E_1} = 2,29 \times 200 = 458,01;$$  
where $REV_{E_1}$ is the revenue collected at entry point 1

$$\sum REV = REV_{E_1} + REV_{E_2} = 477,81$$

This result is very close to the previously calculated $R_E$ of 478,47

Setting $T_{XD_2}$ to 0,54:

$$REV_{XD_2} = T_{XD_2} \times BC_{XD_2} = 0,54 \times 10 = 5,40;$$  
where $REV_{XD_2}$ is the revenue collected at exit point D2

Then,

$$T_{X_1} = 5,05 \times T_{XD_2} = 2,73$$

$$REV_{X_1} = T_{X_1} \times BC_{X_1} = 2,73 \times 120 = 327,56;$$  
where $REV_{X_1}$ is the revenue collected at exit point 1

$$T_{X_2} = 4,41 \times T_{XD_2} = 2,38$$

$$REV_{X_2} = T_{X_2} \times BC_{X_2} = 2,38 \times 20 = 47,59;$$  
where $REV_{X_2}$ is the revenue collected at exit point 2

$$T_{XD_1} = 3,32 \times T_{XD_2} = 1,79$$

$$REV_{XD_1} = T_{XD_1} \times BC_{XD_1} = 1,79 \times 80 = 143,57;$$  
where $REV_{XD_1}$ is the revenue collected at exit point D1

$$\sum REV = REV_{X_1} + REV_{X_2} + REV_{XD_1} + REV_{XD_2} = 524,13$$
This result is very close to the previously calculated $R_X$ of 521,53

6 Matrix approach

This matrix model is a simplified version of the Italian entry-exit matrix model, and it is based on the same assumptions of the capacity-weighted distance – variant A (CWD) model, in order to favour comparability of outcomes.

It must be stressed, however, that many inputs which are needed for our model were missing in the CWD example, therefore we had to make further assumptions in order to make the model work. Since these assumptions have a degree of arbitrariness, and they may strongly influence the outcomes, we believe comparability is a questionable issue as long as a full set of common, and possibly realistic, inputs is not given as the starting point of each model. In particular, our model requires a full “map” of the physical network whereby each portion of grid ("segment") is associated a physical capacity, a length and, if needed for the purposes of cost driver calculation, a corresponding standard investment cost; also, a representation of all entry/exit paths (and the segments they are composed of) is needed.

We derived the missing inputs from the CWD model as follows:

- we assume virtual and physical paths correspond, thus there are no shared network segments;

- each entry-exit path capacity is the exit capacity averaged with the corresponding entry capacity;

- the sum of all entry-exit path capacities leading to an exit point is the exit point capacity.

Regarding the standard investment costs, we used an index derived from the actual index used in the Italian model.

This simplified model simply requires forecasts on booked capacity at entries and exits. However, in case of a different treatment of counter-flow segments in an entry/exit path (which is accounted for in the Italian case), assumptions on gas flows at peak would be needed.

It must be pointed out that such a network structure (where each entry is connected to each exit, but without shared segments) is rarely observed in practice. Nonetheless, we developed our model based on these assumptions in order to provide a certain degree of comparability with the CWD model.

6.3 Main methodology

i. Defining a cost driver and applying the cost driver to network segments

When defining a cost driver (which we called “Normalized Transport Cost”, TC), our simplified model takes into account the following features of each segment:

a) technical capacity (Mcm/day);

b) standard investment cost index in relation to capacity (IC);

c) length.

The IC index can be defined by the TSO and refers to investment costs in relation to capacity, which means taking into account mainly economies of scale. The TC is defined as:

\[ uTC = IC/capacity \]

\[ TC = (IC/capacity) \times length \]

Table 12 provides an overview of the uTC for our model, while

---

7 see section 3.4.1.4 of the Revised chapter on Cost Allocation and determination of the reference price
Table 9 defines the TC for each network segment, based on capacity and length.

### Table 12: Unit transport cost computation

<th>Std investment cost index</th>
<th>uTC</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.3</td>
<td>0.40</td>
<td>0.12</td>
</tr>
<tr>
<td>5</td>
<td>0.50</td>
<td>0.10</td>
</tr>
<tr>
<td>6.7</td>
<td>0.70</td>
<td>0.10</td>
</tr>
<tr>
<td>10</td>
<td>0.80</td>
<td>0.08</td>
</tr>
<tr>
<td>15</td>
<td>1.00</td>
<td>0.07</td>
</tr>
</tbody>
</table>

#### ii. Creating a matrix of cost drivers

Usually, each entry-exit path is assigned a TC which is the sum of the segments TC composing the path. However, in this simplified model each entry-exit path is only composed of one segment, therefore the matrix of cost driver is easily built (Table 13).

### Table 13: Matrix of cost drivers

<table>
<thead>
<tr>
<th>TC</th>
<th>EX1</th>
<th>EX2</th>
</tr>
</thead>
<tbody>
<tr>
<td>EN1</td>
<td>24.2</td>
<td>30.0</td>

<tr>
<td>EN2</td>
<td>41.8</td>
<td>40.0</td>
</tr>
<tr>
<td>EN3</td>
<td>48.0</td>
<td>6.7</td>
</tr>
</tbody>
</table>

#### iii. Defining entry/exit tariffs

Tariffs at entry \(T_{En}\) and exit \(T_{Ex}\) are defined by solving the following function:

\[
\min \sum_{en,ex} \varepsilon_{en,ex}^2
\]

Whereby

\[
TC_{en,ex} = T_{en} + T_{ex} + \varepsilon_{en,ex}
\]

Therefore, the function to be solved can also be seen as

\[
\min \sum_{en,ex} (T_{En} + T_{Ex} - TC)^2
\]

A constraint also applies to avoid negative tariffs.

Results of the minimization function are given in Table 14.
Table 14: results of the minimization function

<table>
<thead>
<tr>
<th>$T_{En}$</th>
<th>EN1</th>
<th>7.3</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EN2</td>
<td>24.9</td>
</tr>
<tr>
<td></td>
<td>EN3</td>
<td>2.2</td>
</tr>
<tr>
<td>$T_{Ex}$</td>
<td>EX1</td>
<td>16.9</td>
</tr>
<tr>
<td></td>
<td>EX2</td>
<td>4.5</td>
</tr>
</tbody>
</table>

iv. Scaling, entry exit split

Tariffs must then be scaled to meet allowed revenues (100 000), according to forecasts on booked capacity (Table 15).

Table 15: tariffs after rescaling, before entry-exit split

<table>
<thead>
<tr>
<th>Entry</th>
<th>Tariff</th>
<th>Booked capacity (Mmc/year)</th>
<th>Revenues (€)</th>
</tr>
</thead>
<tbody>
<tr>
<td>EN1</td>
<td>911.9</td>
<td>7.8</td>
<td>7113</td>
</tr>
<tr>
<td>EN2</td>
<td>3094.7</td>
<td>13.8</td>
<td>42707</td>
</tr>
<tr>
<td>EN3</td>
<td>275.0</td>
<td>25.0</td>
<td>6875</td>

<td>25.0</td>
<td>13856</td>
</tr>
<tr>
<td>Tot</td>
<td>39.0</td>
<td>43306</td>
<td></td>
</tr>
</tbody>
</table>

Allowed revenues 100000

Finally, tariffs are further scaled to meet the 50/50 entry/exit split target (Table 16).
